

LECTURE NOTES NONLINEAR OPTIMIZATION

SPRING SEMESTER 2023

Roland Herzog*

2023-06-03

*Interdisciplinary Center for Scientific Computing, Heidelberg University, 69120 Heidelberg, Germany
(roland.herzog@iwr.uni-heidelberg.de, <https://scoop.iwr.uni-heidelberg.de/team/roland-herzog>).

These lecture notes are partly based on content from the books [Nocedal, Wright, 2006](#); [Ulbrich, Ulbrich, 2012](#) as well as on previous lecture notes by Roland Herzog and Gerd Wachsmuth (BTU Cottbus).

Material for 14 weeks.

Please send comments to roland.herzog@iwr.uni-heidelberg.de.

Chapter 0 Introduction

§ 1 ELEMENTARY NOTIONS

Mathematical optimization is about solving problems of the form

$$\left. \begin{array}{lll} \text{Minimize} & f(x) & \text{where } x \in \Omega \quad \textbf{(objective function)} \\ \text{subject to} & g_i(x) \leq 0 & \text{for } i = 1, \dots, n_{\text{ineq}} \quad \textbf{(inequality constraints)} \\ & \text{and } h_j(x) = 0 & \text{for } j = 1, \dots, n_{\text{eq}}. \quad \textbf{(equality constraints)} \end{array} \right\} \quad (1.1)$$

$\Omega \subseteq \mathbb{R}^n$ is the **basic set** and x is the **optimization variable** or simply the **variable** of the problem. We will assume that

- the functions $f, g_i, h_j: \mathbb{R}^n \rightarrow \mathbb{R}$ are sufficiently smooth (C^2 functions),
- we have a finite number (possibly zero) of inequality and equality constraints, i. e., n_{ineq} and n_{eq} are in \mathbb{N}_0 .

We will assume $\Omega = \mathbb{R}^n$, i. e., we consider only **continuous optimization** problems and without implicit constraints.

Definition 1.1 (Elementary notions).

(i) *The set*

$$F := \{x \in \mathbb{R}^n \mid g_i(x) \leq 0 \text{ for all } i = 1, \dots, n_{\text{ineq}}, h_j(x) = 0 \text{ for all } j = 1, \dots, n_{\text{eq}}\} \quad (1.2)$$

*associated with an optimization problem (1.1) is termed the **feasible set**. Any $x \in F$ is termed a **feasible point**.*

(ii) *The inequality $g_i(x) \leq 0$ is called **active** at a point x if $g_i(x) = 0$ holds. It is called **inactive** in case $g_i(x) < 0$. It is called **violated** if $g_i(x) > 0$ holds.*

(iii) *The value*

$$f^* := \inf \{f(x) \mid x \in F\}$$

*is termed the **infimal value** of problem (1.1).*

(iv) *In case $F = \emptyset$, the problem (1.1) is said to be **infeasible**. In that case, we have $f^* = +\infty$. In case $f^* = -\infty$, the problem is said to be **unbounded**.*

- (v) A point $x^* \in F$ is a **global minimizer** or **globally optimal solution** of (1.1) if

$$f(x^*) \leq f(x) \text{ for all } x \in F$$

holds. Equivalently, $x^* \in F$ is a global minimizer if $f(x^*) = f^*$ holds. In this case, the infimal value f^* is also referred to as the **global minimum** or **globally optimal value** of (1.1).

- (vi) A global minimizer x^* is **strict** in case

$$f(x^*) < f(x) \text{ for all } x \in F, x \neq x^*.$$

- (vii) A point $x^* \in F$ is a **local minimizer** or **locally optimal solution** of (1.1) if there exists a neighborhood $U(x^*)$ such that

$$f(x^*) \leq f(x) \text{ for all } x \in F \cap U(x^*)$$

holds. In this case, $f(x^*)$ is also referred to as a **local minimum** or a **locally optimal value** of (1.1).

- (viii) A local minimizer x^* is **strict** in case

$$f(x^*) < f(x) \text{ for all } x \in F \cap U(x^*), x \neq x^*.$$

- (ix) An optimization problem (1.1) is **solvable** if it has at least one global minimizer, i. e., if the optimal value is attained at some point. Otherwise, the problem is **unsolvable**.

Definition 1.2 (Classification of optimization problems).

- (i) An optimization problem (1.1) is said to be **unconstrained** in case $n_{\text{ineq}} = n_{\text{eq}} = 0$. Otherwise, it is said to be **equality constrained** and/or **inequality constrained**.

- (ii) Inequality constraints of the simple kind

$$\ell_i \leq x_i \leq u_i, \quad i = 1, \dots, n$$

with bounds $\ell_i \in \mathbb{R} \cup \{-\infty\}$ and $u_i \in \mathbb{R} \cup \{\infty\}$ are called **bound constraints**.

- (iii) When f is a quadratic polynomial and g and h are affine linear functions, then (1.1) is called a **quadratic optimization problem** or a **quadratic program (QP)**.

- (iv) In the general case, i. e., when (1.1) is not a quadratic program, we refer to (1.1) as a **nonlinear optimization problem** or **nonlinear program (NLP)**.

The emphasis in this class is on numerical techniques for unconstrained and constrained nonlinear programs. We will see that fast algorithms take into account the optimality conditions of the respective problem. Therefore we will also discuss optimality conditions.

We will begin in [Chapter 1](#) with algorithms for unconstrained optimization. Some of the content was already part of the class *Grundlagen der Optimierung* ([Herzog, 2022](#)), but we will revisit the material in more detail here. The theory for constrained problems is relatively involved and merits its own chapter ([Chapter 2](#)). We will subsequently discuss major algorithmic ideas for constrained problems in [Chapter 3](#). Finally, we will review in [Chapter 4](#) some computer-aided techniques to obtain derivatives of functions, which the algorithms under consideration generally require.

Throughout the class, we will emphasize the connections between optimization and numerical linear algebra.

§ 2 NOTATION AND BACKGROUND MATERIAL

In these lecture notes we use color codes for **definitions** and **highlights**. The natural numbers are $\mathbb{N} = \{1, 2, \dots\}$, and we write \mathbb{N}_0 for $\mathbb{N} \cup \{0\}$. We denote open intervals by (a, b) and closed intervals by $[a, b]$. We usually use Latin capital letters for matrices, Latin lowercase letters for vectors and Greek or Latin lowercase letters for scalars. We use Id for the identity matrix. We distinguish the vector space \mathbb{R}^n of column vectors from the vector space \mathbb{R}_n of row vectors.

§ 2.1 VECTOR NORMS

An **inner product** (\cdot, \cdot) on \mathbb{R}^n is a symmetric and positive definite bilinear form, i. e., a map $\mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ with the following properties:

$$(x, y) = (y, x) \quad (\text{symmetry}) \quad (2.1a)$$

$$(\alpha_1 x_1 + \alpha_2 x_2, y) = \alpha_1 (x_1, y) + \alpha_2 (x_2, y) \quad (\text{bilinearity part 1}) \quad (2.1b)$$

$$(x, \beta_1 y_1 + \beta_2 y_2) = \beta_1 (x, y_1) + \beta_2 (x, y_2) \quad (\text{bilinearity part 2}) \quad (2.1c)$$

$$(x, x) \geq 0 \quad \text{and} \quad x \neq 0 \Rightarrow (x, x) > 0 \quad (\text{positive definiteness}) \quad (2.1d)$$

for all $x, x_1, x_2, y, y_1, y_2 \in \mathbb{R}^n$ and all $\alpha_1, \alpha_2, \beta_1, \beta_2 \in \mathbb{R}$.

Inner products on \mathbb{R}^n are in one-to-one correspondence with symmetric and positive definite (s. p. d.) $n \times n$ matrices. That is, every s. p. d. matrix $M \in \mathbb{R}^{n \times n}$ induces an inner product

$$(x, y)_M := x^T M y,$$

and, on the other hand, every inner product (\cdot, \cdot) on \mathbb{R}^n is induced by an s. p. d. matrix M . For simplicity, we will refer to M itself as the inner product it induces, or use the term “ M -inner product”.

Every inner product $(\cdot, \cdot)_M$ induces a norm¹ by way of

$$\|x\|_M := \sqrt{x^T M x}. \quad (2.2)$$

¹We are only considering norms induced by inner products.

In particular, the Euclidean inner product $x^\top y$ corresponds to the identity matrix $M = \text{Id}$, and we denote the associated norm by $\|x\|$. We won't be writing $\langle x, y \rangle$ or $x \cdot y$ for the Euclidean inner product.

Notice that for vectors $x, y \in \mathbb{R}^n$, we have

$$\begin{aligned} a^\top b &= a^\top M^{-1} M b \\ &\leq \|M^{-1} a\|_M \|b\|_M \quad \text{by the Cauchy-Schwarz inequality w.r.t. the } M\text{-inner product} \\ &= \|a\|_{M^{-1}} \|b\|_M. \end{aligned} \tag{2.3}$$

§ 2.2 MATRIX NORMS

A matrix $A \in \mathbb{R}^{m \times n}$ represents a linear map by way of $\mathbb{R}^n \ni x \mapsto Ax \in \mathbb{R}^m$. When \mathbb{R}^n is equipped with the M_1 -inner product and \mathbb{R}^m is equipped with the M_2 -inner product, we define the **matrix norm** or **operator norm** of A as

$$\|A\|_{M_2 \leftarrow M_1} := \max_{x \neq 0} \frac{\|Ax\|_{M_2}}{\|x\|_{M_1}}. \tag{2.4}$$

We thus have

$$\|Ax\|_{M_2} \leq \|A\|_{M_2 \leftarrow M_1} \|x\|_{M_1} \quad \text{for all } x \in \mathbb{R}^n. \tag{2.5}$$

When M_1 and M_2 are both the Euclidean inner products, $\|A\|_{\text{Id} \leftarrow \text{Id}}$ or simply $\|A\|$ is the largest singular value of A . In the general case, $\|A\|_{M_2 \leftarrow M_1}$ is the largest singular value of a suitably generalized singular value decomposition.

There are matrix norm which are not operator norms. The most prominent one is induced by the inner product

$$A : B := \text{trace}(A^\top B) = \sum_{i=1}^m \sum_{j=1}^n a_{ij} b_{ij}. \tag{2.6}$$

The associated norm

$$\|A\|_F := \left(\sum_{i=1}^m \sum_{j=1}^n a_{ij}^2 \right)^{1/2} \tag{2.7}$$

is termed the **Frobenius norm** of A .

§ 2.3 EIGENVALUES AND EIGENVECTORS

Every symmetric matrix $A \in \mathbb{R}^{n \times n}$ possesses an orthogonal transformation to a diagonal matrix, known as **eigen decomposition** or **spectral decomposition**. That is, there exists an orthogonal matrix $V \in \mathbb{R}^{n \times n}$ and a diagonal matrix $\Lambda \in \mathbb{R}^{n \times n}$, such that

$$AV = V\Lambda, \quad \text{i. e.,} \quad A = V\Lambda V^\top \tag{2.8}$$

holds. The diagonal of Λ contains the eigenvalues λ_i , and the columns v_i of V are the corresponding eigenvectors. This decomposition yields the complete solution to the **eigenvalue problem**

$$Av = \lambda v. \tag{2.9}$$

We also work with the **generalized eigenvalue problem**

$$A v = \lambda M v \quad (2.10)$$

for the particular case where A is still symmetric and the second matrix $M \in \mathbb{R}^{n \times n}$ is s. p. d. There exists an analogous **generalized spectral decomposition**

$$A V = M V \Lambda, \quad \text{i. e.,} \quad A = M V \Lambda V^T M, \quad (2.11)$$

where now V is orthogonal w.r.t. the M -inner product, i. e., $V^T M V = \text{Id}$ holds. This implies $V V^T = M^{-1}$. We also refer to the solutions of (2.10) as the **eigenvalues/eigenvectors of A w.r.t. M** or **eigenvalues/eigenvectors of the pair $(A; M)$** .

In view of the **Courant-Fischer theorem** for (generalized) eigenvalues of symmetric matrices, the **generalized Rayleigh quotient** of A w.r.t. M satisfies

$$\lambda_{\min}(A; M) \leq \frac{x^T A x}{x^T M x} \leq \lambda_{\max}(A; M) \quad \text{for all } x \neq 0. \quad (2.12)$$

The eigenvectors associated with the smallest and largest generalized eigenvalues $\lambda_{\min}(A; M)$ and $\lambda_{\max}(A; M)$ satisfy the first respectively the second inequality with equality. Using (2.3) and (2.5), we also have

$$-\|A\|_{M^{-1} \leftarrow M} \leq -\frac{\|x\|_M \|A x\|_{M^{-1}}}{\|x\|_M^2} \leq \frac{x^T A x}{\|x\|_M^2} \leq \frac{\|x\|_M \|A x\|_{M^{-1}}}{\|x\|_M^2} \leq \|A\|_{M^{-1} \leftarrow M}$$

and thus

$$\lambda_{\max}(H; M) \leq \|H\|_{M^{-1} \leftarrow M} \quad \text{and} \quad -\lambda_{\min}(H; M) \leq \|H\|_{M^{-1} \leftarrow M}. \quad (2.13)$$

Notice that the generalized eigenvalue problems (2.10) and

$$M v = \lambda M A^{-1} M v \quad (2.14a)$$

as well as

$$A M^{-1} A v = \lambda A v \quad (2.14b)$$

have the same eigenvalues and eigenvectors (provided ~~in case of (2.14a)~~ that A is not only symmetric but also invertible) since $M v = \lambda M A^{-1} M v \Leftrightarrow v = \lambda A^{-1} M v \Leftrightarrow A v = \lambda M v$ and $A M^{-1} A v = \lambda A v \Leftrightarrow M^{-1} A v = \lambda v \Leftrightarrow A v = \lambda M v$. Consequently, we obtain the following estimate for the generalized Rayleigh quotients associated with (2.14):

$$\lambda_{\min}(A; M) \leq \frac{x^T M x}{x^T M A^{-1} M x} \leq \lambda_{\max}(A; M) \quad \text{for all } x \neq 0, \quad (2.15a)$$

$$\lambda_{\min}(A; M) \leq \frac{x^T A M^{-1} A x}{x^T A x} \leq \lambda_{\max}(A; M) \quad \text{for all } x \neq 0. \quad (2.15b)$$

Every s. p. d. matrix $A \in \mathbb{R}^{n \times n}$ possesses a unique s. p. d. **matrix square root** $A^{1/2}$. When $A = V \Lambda V^T$ is a spectral decomposition of A with orthogonal V , then

$$A^{1/2} = V \Lambda^{1/2} V^T \quad (2.16)$$

holds. Herein, $\Lambda^{1/2}$ is the elementwise square root of the diagonal matrix Λ .

§ 2.4 KANTOROVICH INEQUALITY

Suppose that A is an s. p. d. matrix. Let us denote the extremal eigenvalues by $\alpha := \lambda_{\min}(A)$ and $\beta := \lambda_{\max}(A)$. Moreover, since A is s. p. d., it follows that its **condition number**² is given by

$$\kappa := \frac{\beta}{\alpha}. \quad (2.17)$$

Notice that a condition number always satisfies $\kappa \geq 1$. From the Rayleigh quotient estimate (2.12) (with $M = \text{Id}$), we have

$$\frac{x^T A x}{\|x\|^2} \leq \beta.$$

Moreover, since the eigenvalues of A^{-1} are the reciprocals of those of A , we have $\lambda_{\max}(A^{-1}) = 1/\lambda_{\min}(A) = 1/\alpha$ and thus

$$\frac{x^T A^{-1} x}{\|x\|^2} \leq \frac{1}{\alpha}.$$

These inequalities hold for all $x \in \mathbb{R}^n \setminus \{0\}$, and they imply

$$\frac{(x^T A x) (x^T A^{-1} x)}{\|x\|^4} \leq \frac{\beta}{\alpha}.$$

This estimate, however, is not sharp in general. (**Quiz 2.1:** Can you explain why not?) The Kantorovich inequality improves this estimate.

Lemma 2.1 (Kantorovich inequality). *Suppose that $A \in \mathbb{R}^{n \times n}$ is s. p. d., $\alpha := \lambda_{\min}(A)$ and $\beta := \lambda_{\max}(A)$ are its extremal eigenvalues, and $\kappa = \beta/\alpha$ is its condition number. Then*

$$1 \leq \frac{(x^T A x) (x^T A^{-1} x)}{\|x\|^4} \leq \frac{(\alpha + \beta)^2}{4 \alpha \beta} \leq \frac{\beta}{\alpha} \quad (2.18a)$$

holds for all $x \in \mathbb{R}^n \setminus \{0\}$, or equivalently, in terms of the condition number $\kappa = \beta/\alpha$,

$$1 \leq \frac{(x^T A x) (x^T A^{-1} x)}{\|x\|^4} \leq \frac{(\kappa + 1)^2}{4 \kappa} \leq \kappa. \quad (2.18b)$$

Proof. The Cauchy-Schwarz inequality implies

$$\|x\|^2 = x^T x = x^T A^{-1/2} A^{1/2} x \leq \|A^{-1/2} x\| \|A^{1/2} x\|.$$

By squaring this, we obtain

$$\|x\|^4 \leq \|A^{-1/2} x\|^2 \|A^{1/2} x\|^2 = (x^T A x) (x^T A^{-1} x)$$

and thus the lower bound in (2.18).

²Generally, the condition of an invertible matrix A is $\kappa = \|A\| \|A^{-1}\|$. This is equal to $\sigma_{\max}(A)/\sigma_{\min}(A)$ with the extremal singular values $\sigma_{\max}(A)$ and $\sigma_{\min}(A)$. Since A is symmetric, its singular values are just the absolute values of its eigenvalues, and since A is also positive definite, we have $\sigma_{\max}(A) = \lambda_{\max}(A) = \beta$ and $\sigma_{\min}(A) = \lambda_{\min}(A) = \alpha$.

From here on, the proof follows [Anderson, 1971](#), as reproduced in the Master's thesis [Alpargu, 1996](#), Section 1.2.2. Let $\lambda_1, \dots, \lambda_n > 0$ be the eigenvalues of A (in any order), and let v_1, \dots, v_n be an orthonormal set of associated eigenvectors. We represent $x \in \mathbb{R}^n \setminus \{0\}$ as $x = \sum_{i=1}^n \gamma_i v_i$. Suppose, w.l.o.g., that $\|x\|^2 = \sum_{i=1}^n \gamma_i^2 = 1$ holds. Inserting the representation of x yields

$$\frac{(x^T A x) (x^T A^{-1} x)}{\|x\|^4} = \underbrace{\left[\sum_{i=1}^n \lambda_i \gamma_i^2 \right]}_{=\mathbb{E}(T)} \underbrace{\left[\sum_{i=1}^n \frac{1}{\lambda_i} \gamma_i^2 \right]}_{=\mathbb{E}(1/T)}.$$

It is helpful to think about the two factors on the right-hand side as expected values of a “random variable” T and $1/T$, respectively. Here T takes the values $\lambda_i \in [\alpha, \beta]$ with “probability” γ_i^2 . For any $0 < \alpha \leq T \leq \beta$, we can estimate

$$0 \leq (\beta - T) (T - \alpha) = (\beta + \alpha - T) T - \alpha \beta,$$

and thus

$$\frac{1}{T} \leq \frac{\alpha + \beta - T}{\alpha \beta}.$$

Taking the expected value, this implies

$$\begin{aligned} \mathbb{E}(T) \mathbb{E}(1/T) &\leq \mathbb{E}(T) \frac{\alpha + \beta - \mathbb{E}(T)}{\alpha \beta} \\ &= \frac{(\alpha + \beta)^2}{4 \alpha \beta} - \frac{1}{\alpha \beta} \left[\mathbb{E}(T) - \frac{1}{2}(\alpha + \beta) \right]^2 \\ &\leq \frac{(\alpha + \beta)^2}{4 \alpha \beta}. \end{aligned}$$

This shows that essential upper bound in (2.18). The remaining inequality follows directly from $0 < \alpha \leq \beta$. \square

Instead of the Euclidean norm, we can also use the norm induced by the M -inner product.

Corollary 2.2 (Generalized Kantorovich inequality). *Suppose that $A \in \mathbb{R}^{n \times n}$ and M are both s. p. d., $\alpha := \lambda_{\min}(A; M)$ and $\beta := \lambda_{\max}(A; M)$ are the extremal generalized eigenvalues of A w.r.t. M . Then*

$$1 \leq \frac{(x^T A x) (x^T M A^{-1} M x)}{\|x\|_M^4} \leq \frac{(\alpha + \beta)^2}{4 \alpha \beta} \leq \frac{\beta}{\alpha} \quad (2.19a)$$

holds for all $x \in \mathbb{R}^n \setminus \{0\}$, or equivalently, in terms of the **generalized condition number** $\kappa = \beta/\alpha$,

$$1 \leq \frac{(x^T A x) (x^T A^{-1} x)}{\|x\|_M^4} \leq \frac{(\kappa + 1)^2}{4 \kappa} \leq \kappa. \quad (2.19b)$$

We do not give a proof of [Corollary 2.2](#) here; see for instance

[Herzog, 2022](#), Folgerung 4.14.

§ 2.5 FUNCTIONS AND DERIVATIVES

- Given a function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ and $x \in \mathbb{R}^n$, the derivative of the partial function $t \mapsto f(x + t e^{(i)})$ at $t = 0$ is the i -th **partial derivative** of f at x , briefly: $\frac{\partial}{\partial x_i} f(x)$. Here $e^{(i)} = (0, \dots, 0, 1, 0, \dots, 0)^\top$ is one of the standard basis vectors of \mathbb{R}^n . In other words,

$$\frac{\partial}{\partial x_i} f(x) = \lim_{t \rightarrow 0} \frac{f(x + t e^{(i)}) - f(x)}{t}.$$

- More generally, the derivative of the function $t \mapsto f(x + t d)$ at $t = 0$ is the **(two-sided) directional derivative** of f at x in the direction $d \in \mathbb{R}^n$, briefly:

$$\frac{\partial}{\partial d} f(x) = \lim_{t \rightarrow 0} \frac{f(x + t d) - f(x)}{t}.$$

- The right-sided derivative of the function $t \mapsto f(x + t d)$ at $t = 0$ is the **(one-sided) directional derivative** of f at x in the direction $d \in \mathbb{R}^n$, briefly:

$$f'(x; d) = \lim_{t \searrow 0} \frac{f(x + t d) - f(x)}{t}.$$

- A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is **differentiable** at $x \in \mathbb{R}^n$ if there exists a row vector $v \in \mathbb{R}_n$ such that

$$\frac{f(x + d) - f(x) - v d}{\|d\|} \rightarrow 0 \quad \text{for } d \rightarrow 0.$$

In this case, the vector v is the **(total) derivative** of f at x , and it is denoted by $f'(x)$.

- When $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable at $x \in \mathbb{R}^n$, then

$$f'(x) = \left(\frac{\partial f(x)}{\partial x_1}, \quad \dots, \quad \frac{\partial f(x)}{\partial x_n} \right) \in \mathbb{R}_n.$$

The transposed vector (a column vector)

$$\nabla f(x) = \begin{pmatrix} \frac{\partial f(x)}{\partial x_1} \\ \vdots \\ \frac{\partial f(x)}{\partial x_n} \end{pmatrix} = f'(x)^\top \in \mathbb{R}^n$$

is the **gradient** (w.r.t. the Euclidean inner product) of f at x .

- When $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable at $x \in \mathbb{R}^n$, then

$$f'(x; d) = \frac{\partial}{\partial d} f(x) = f'(x) d$$

holds for all $d \in \mathbb{R}^n$. That is, the one-sided and two-sided directional derivatives of f at x agree, and they can be evaluated by applying the derivative $f'(x)$ to the direction d .

- A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is **continuously partially differentiable** or briefly: $C^1(\mathbb{R}^n, \mathbb{R})$, if all partial derivatives $\frac{\partial f(x)}{\partial x_i}$, as functions of x , are continuous. C^1 -functions are differentiable, and the derivative f' is continuous.
- A vector-valued function $F: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is **differentiable** at $x \in \mathbb{R}^n$ if all component functions F_1, \dots, F_m are differentiable at x . In this case, the derivative $F'(x)$ is given by the **Jacobian** of F at x , i. e., by

$$\begin{pmatrix} \frac{\partial F_1(x)}{\partial x_1} & \dots & \frac{\partial F_1(x)}{\partial x_n} \\ \vdots & & \vdots \\ \frac{\partial F_m(x)}{\partial x_1} & \dots & \frac{\partial F_m(x)}{\partial x_n} \end{pmatrix} \in \mathbb{R}^{m \times n}.$$

- F is **continuously partially differentiable** if all entries of the Jacobian are continuous as functions of x . C^1 -functions are differentiable, and the derivative F' is continuous.
- A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is **twice differentiable** at $x \in \mathbb{R}^n$ if f is differentiable in a neighborhood of x and the derivative $x \mapsto f'(x) \in \mathbb{R}^n$ is differentiable at x . In this case, the second derivative $f''(x)$ is given by the **Hessian** of f at x , i. e., by the matrix of second-order partial derivatives

$$\left(\frac{\partial^2 f(x)}{\partial x_i \partial x_j} \right)_{i,j=1}^n = \begin{pmatrix} \frac{\partial^2 f(x)}{\partial x_1^2} & \frac{\partial^2 f(x)}{\partial x_1 \partial x_2} & \dots & \frac{\partial^2 f(x)}{\partial x_1 \partial x_n} \\ \frac{\partial^2 f(x)}{\partial x_2 \partial x_1} & \frac{\partial^2 f(x)}{\partial x_2^2} & \dots & \frac{\partial^2 f(x)}{\partial x_2 \partial x_n} \\ \vdots & \vdots & & \vdots \\ \frac{\partial^2 f(x)}{\partial x_n \partial x_1} & \frac{\partial^2 f(x)}{\partial x_n \partial x_2} & \dots & \frac{\partial^2 f(x)}{\partial x_n^2} \end{pmatrix}.$$

When f is twice differentiable at x , then the Hessian is symmetric by Schwarz' theorem.³

- A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is **twice continuously partially differentiable** or briefly: $C^2(\mathbb{R}^n, \mathbb{R})$, if all entries of the Hessian are continuous as functions of x . C^2 -functions are twice differentiable.

§ 2.6 TAYLOR'S THEOREM

We are going to state Taylor's theorem in two variants:

Theorem 2.3 (Taylor, see Cartan, 1967, Theorem 5.6.3). *Suppose that $G \subseteq \mathbb{R}^n$ open, $k \in \mathbb{N}_0$ and $f: G \rightarrow \mathbb{R}$ k times differentiable, and $(k+1)$ times differentiable at $x^{(0)} \in G$. Then for all $\varepsilon > 0$, there exists $\delta > 0$ such that*

$$\text{in case } k = 0 : \quad |f(x^{(0)} + d) - f(x^{(0)}) - f'(x^{(0)})d| \leq \varepsilon \|d\|,$$

$$\text{in case } k = 1 : \quad |f(x^{(0)} + d) - f(x^{(0)}) - f'(x^{(0)})d - \frac{1}{2}d^T f''(x^{(0)})d| \leq \varepsilon \|d\|^2.$$

for all $\|d\| < \delta$.

³See for instance Cartan, 1967, Proposition 5.2.2

Theorem 2.4 (Taylor, see Geiger, Kanzow, 1999, Satz A.2 or Heuser, 2002, Satz 168.1).

Suppose that $G \subseteq \mathbb{R}^n$ is open, $k \in \mathbb{N}_0$ and $f: G \rightarrow \mathbb{R}$ $(k+1)$ times continuously partially differentiable, briefly a $C^{k+1}(G, \mathbb{R})$ function. Suppose that $x^{(0)}$ and $x^{(0)} + d$ and the entire line segment between them lie in G . Then there exists $\xi \in (0, 1)$ such that

$$\text{in case } k = 0: \quad f(x^{(0)} + d) = f(x^{(0)}) + f'(x^{(0)} + \xi d) d \quad (\text{mean value theorem}),$$

$$\text{in case } k = 1: \quad f(x^{(0)} + d) = f(x^{(0)}) + f'(x^{(0)}) d + \frac{1}{2} d^T f''(x^{(0)} + \xi d) d.$$

§ 2.7 CONVERGENCE RATES

We denote (vector-valued) sequences $\mathbb{N} \rightarrow \mathbb{R}^n$ by $(x^{(k)})$ and not (x_k) etc., in order to avoid a conflict of notation with the components of a vector $x = (x_1, \dots, x_n)^T \in \mathbb{R}^n$. The **subsequence** of $(x^{(k)})$ obtained by the strictly increasing sequence $\mathbb{N} \ni \ell \mapsto k^{(\ell)} \in \mathbb{N}$ is denoted by $(x^{(k^{(\ell)})})$.

We introduce various convergence rates for sequences in order to characterize the speed of convergence, e. g., of iterates in an algorithm.

Definition 2.5 (Q-convergence rates⁴).

Suppose that $(x^{(k)}) \subset \mathbb{R}^n$ is a sequence and $x^* \in \mathbb{R}^n$. Moreover, let M be an inner product on \mathbb{R}^n .

(i) $(x^{(k)})$ converges to x^* (at least) **Q-linearly** w.r.t. the M -norm if there exists $c \in (0, 1)$ such that

$$\|x^{(k+1)} - x^*\|_M \leq c \|x^{(k)} - x^*\|_M \quad \text{for all } k \in \mathbb{N} \text{ sufficiently large.}$$

(ii) $(x^{(k)})$ converges to x^* (at least) **Q-superlinearly** w.r.t. the M -norm if there exists a null sequence $(\varepsilon^{(k)})$ such that

$$\|x^{(k+1)} - x^*\|_M \leq \varepsilon^{(k)} \|x^{(k)} - x^*\|_M \quad \text{for all } k \in \mathbb{N}.$$

(iii) Suppose that $x^{(k)} \rightarrow x^*$. $(x^{(k)})$ converges to x^* (at least) **Q-quadratically** w.r.t. the M -norm if there exists $C > 0$ such that

$$\|x^{(k+1)} - x^*\|_M \leq C \|x^{(k)} - x^*\|_M^2 \quad \text{for all } k \in \mathbb{N}.$$

Note: Q-superlinear and Q-quadratic convergence of a sequence are independent of the norm (inner product) M . However, the property of Q-linear convergence can be lost when changing the norm.

Definition 2.6 (R-convergence rates⁵).

Suppose that $(x^{(k)}) \subset \mathbb{R}^n$ is a sequence and $x^* \in \mathbb{R}^n$. Moreover, let M be an inner product on \mathbb{R}^n .

⁴“Q” stands for “quotient”.

⁵“R” stands for “root”.

- (i) $(x^{(k)})$ converges to x^* (at least) **R-linearly** w.r.t. the M -norm if there exists a null sequence $(\varepsilon^{(k)})$ such that

$$\|x^{(k)} - x^*\|_M \leq \varepsilon^{(k)} \quad \text{for all } k \in \mathbb{N},$$

and $(\varepsilon^{(k)})$ converges to zero Q -linearly w.r.t. $|\cdot|$.

- (ii) $(x^{(k)})$ converges to x^* (at least) **R-superlinearly** w.r.t. the M -norm if there exists a null sequence $(\varepsilon^{(k)})$ such that

$$\|x^{(k)} - x^*\|_M \leq \varepsilon^{(k)} \quad \text{for all } k \in \mathbb{N},$$

and $(\varepsilon^{(k)})$ converges to zero Q -superlinearly w.r.t. $|\cdot|$.

- (iii) $(x^{(k)})$ converges to x^* (at least) **R-quadratically** w.r.t. the M -norm if there exists a null sequence $(\varepsilon^{(k)})$ such that

$$\|x^{(k)} - x^*\|_M \leq \varepsilon^{(k)} \quad \text{for all } k \in \mathbb{N},$$

and $(\varepsilon^{(k)})$ converges to zero Q -quadratically w.r.t. $|\cdot|$.

Note: The R-convergence modes are slightly weaker than the respective Q-convergence rates. Q-convergence considers the decrease in the distance to the limit $\|x^{(k)} - x^*\|_M$ in every step of the sequence. By contrast, R-convergence considers the decrease overall.

§ 2.8 CONVEXITY

Convexity plays a very important role in optimization in general. In this class, however, we will rely on it only scarcely. We briefly recall here some elements of convexity. You may study [Herzog, 2022](#), § 13 if you wish to have more background information.

Definition 2.7 (Convex set).

A set $C \subseteq \mathbb{R}^n$ is termed **convex** if $x, y \in C$ and $\alpha \in [0, 1]$ imply $\alpha x + (1 - \alpha) y \in C$.

The condition in Definition 2.7 means that the entire line segment between x and y belongs to C .

Definition 2.8 (Convex function).

A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is termed

- (i) **convex** in case

$$f(\alpha x + (1 - \alpha) y) \leq \alpha f(x) + (1 - \alpha) f(y) \quad (2.20)$$

holds for all $x, y \in \mathbb{R}^n$ and $\alpha \in [0, 1]$.

- (ii) **strictly convex** in case

$$f(\alpha x + (1 - \alpha) y) < \alpha f(x) + (1 - \alpha) f(y) \quad (2.21)$$

holds for all $x, y \in \mathbb{R}^n$ and $\alpha \in (0, 1)$.

(iii) μ -strongly convex or strongly convex with parameter $\mu > 0$ in case

$$f(\alpha x + (1 - \alpha)y) + \frac{\mu}{2} \alpha(1 - \alpha) \|x - y\|^2 \leq \alpha f(x) + (1 - \alpha)f(y) \quad (2.22)$$

holds for all $x, y \in \mathbb{R}^n$ and $\alpha \in [0, 1]$.

(iv) **concave** (concave) or **strictly concave** or **constrly concave** if $-f$ is convex or strictly convex or strongly convex, respectively.

Theorem 2.9 (Characterization of convexity via first-order derivatives).

Suppose that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable.

(a) The following are equivalent:

(i) f is convex.

(ii) For all $x, y \in \mathbb{R}^n$,

$$f(x) - f(y) \geq f'(y)(x - y) \quad (2.23)$$

holds.

(iii) For all $x, y \in \mathbb{R}^n$,

$$(f'(x) - f'(y))(x - y) \geq 0 \quad (2.24)$$

holds. Equation (2.24) means that f' is a **monotone operator**.

(b) The following are equivalent:

(i) f is strictly convex.

(ii) For all $x, y \in \mathbb{R}^n$ such that $x \neq y$,

$$f(x) - f(y) > f'(y)(x - y) \quad (2.25)$$

holds.

(iii) For all $x, y \in \mathbb{R}^n$ such that $x \neq y$,

$$(f'(x) - f'(y))(x - y) > 0. \quad (2.26)$$

Equation (2.26) means that f' is a **strictly monotone operator**.

(c) The following are equivalent:

(i) f is strongly convex.

(ii) There exists $\mu > 0$ such that for all $x, y \in \mathbb{R}^n$,

$$f(x) - f(y) \geq f'(y)(x - y) + \frac{\mu}{2} \|x - y\|^2 \quad (2.27)$$

holds.

(iii) There exists $\mu > 0$ such that for all $x, y \in \mathbb{R}^n$,

$$(f'(x) - f'(y))(x - y) \geq \mu \|x - y\|^2. \quad (2.28)$$

Equation (2.28) means that f' is a **strongly monotone operator**.

Theorem 2.10 (Characterization of convexity via second-order derivatives).
Suppose that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is twice differentiable.

(a) The following are equivalent:

(i) f is convex.

(ii) f'' is everywhere positive semidefinite (has only non-negative eigenvalues).

(b) When f'' is everywhere positive definite, then f is strictly convex.

(c) The following are equivalent:

(i) f is strongly convex with parameter $\mu > 0$.

(ii) The smallest eigenvalue of $f''(x)$ satisfies $\lambda_{\min}(f''(x)) \geq \mu > 0$ for all $x \in \mathbb{R}^n$.

§ 2.9 HYPERPLANES AND HALF SPACES

Suppose that $a \in \mathbb{R}^n$, $a \neq 0$ and $\beta \in \mathbb{R}$. Then the set

$$H(a, \beta) := \{x \in \mathbb{R}^n \mid a^\top x = \beta\} \quad (2.29)$$

is termed a **hyperplane** in \mathbb{R}^n with **normal vector** a .

A hyperplane separates \mathbb{R}^n into two closed **half spaces**

$$\begin{aligned} H^-(a, \beta) &:= \{x \in \mathbb{R}^n \mid a^\top x \leq \beta\} && \text{negative half space,} \\ H^+(a, \beta) &:= \{x \in \mathbb{R}^n \mid a^\top x \geq \beta\} && \text{positive half space.} \end{aligned} \quad (2.30)$$

§ 2.10 MISCELLANEA

We denote the **interior** of a set $S \subseteq \mathbb{R}^n$ by $\text{int } S$ and its **closure** by $\text{cl } S$.

Given $\varepsilon > 0$ and $x \in \mathbb{R}^n$,

$$B_\varepsilon^M(x^{(0)}) := \{x \in \mathbb{R}^n \mid \|x - x^{(0)}\|_M < \varepsilon\}$$

denotes the **open ε -ball** w.r.t. the M -norm about $x^{(0)}$. Similarly, the **closed ε -ball** is

$$\text{cl } B_\varepsilon^M(x^{(0)}) := \{x \in \mathbb{R}^n \mid \|x - x^{(0)}\|_M \leq \varepsilon\}.$$

The **ceiling function** $\lceil x \rceil$ returns the smallest integer $\geq x$.

Chapter 1 Numerical Techniques for Unconstrained Optimization Problems

We discuss in this chapter numerical methods for the unconstrained version of (1.1), i. e.,

$$\text{Minimize } f(x) \quad \text{where } x \in \mathbb{R}^n. \quad (\text{UP})$$

The reason for discussing the unconstrained problem first is that we can introduce the essential algorithmic techniques without the difficulties of any constraints present.

Up front, we mention that we can only hope to find *local* minimizers. Determining *global* minimizers is generally much harder and only possible under additional assumptions on the objective, and generally only in relatively small dimensions $n \in \mathbb{N}$. A notable case of an additional assumption is that of a *convex* objective f . In this case, every local minimizer is already a global minimizer. Moreover, the first-order optimality condition is already sufficient for optimality, and we do not require a second-order condition.

§ 3 OPTIMALITY CONDITIONS

We suppose you have seen the following first- and second-order optimality conditions, so we only briefly recall them; see [Herzog, 2022, § 3](#) for more details.

Theorem 3.1 (First-order necessary optimality condition).

Suppose that x^ is a local minimizer of (UP) and that f is differentiable at x^* . Then $f'(x^*) = 0$.*

Proof. Suppose that $d \in \mathbb{R}^n$ is arbitrary. We consider the curve $\gamma: (-\delta, \delta) \rightarrow \mathbb{R}^n$, $\gamma(t) := x^* + t d$. For sufficiently small $\delta > 0$, this curve runs within the neighborhood of local optimality of x^* . This implies that $f \circ \gamma$ has a local minimizer at $t = 0$.

From this local optimality, we infer that the difference quotient satisfies

$$\frac{f(\gamma(t)) - f(\gamma(0))}{t} = \frac{f(x^* + t d) - f(x^*)}{t} \begin{cases} \geq 0 & \text{for } t > 0, \\ \leq 0 & \text{for } t < 0. \end{cases}$$

On the other hand, this difference quotient converges to $f'(x^*) d$ as $t \rightarrow 0$. Consequently, we must have $f'(x^*) d = 0$. Since $d \in \mathbb{R}^n$ was arbitrary, this means $f'(x^*) = 0$. \square

A point $x \in \mathbb{R}^n$ with the property $f'(x) = 0$ is termed a **stationary point** of f .

Theorem 3.2 (Second-order necessary optimality condition).

Suppose that x^* is a local minimizer of (UP) and that f is twice differentiable at x^* . Then the Hessian $f''(x^*)$ is positive semidefinite.¹

Proof. Suppose that $d \in \mathbb{R}^n$ is arbitrary. Wie in Theorem 3.1 we define $\gamma(t) := x^* + t d$ and again consider the objective along the curve, i. e., $\varphi := f \circ \gamma$, which has a local minimizer at $t = 0$. Since φ is twice differentiable at $t = 0$, Theorem 2.3 implies the following: for all $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\left| \varphi(t) - \varphi(0) - \varphi'(0)t - \frac{1}{2}\varphi''(0)t^2 \right| \leq \varepsilon t^2$$

holds for all $|t| < \delta$. In view of Theorem 3.1, $\varphi'(0) = 0$, and the local optimality implies $\varphi(0) \leq \varphi(t)$ for all $|t|$ sufficiently small. We thus obtain

$$-\frac{1}{2}\varphi''(0)t^2 \leq \varphi(t) - \varphi(0) - \frac{1}{2}\varphi''(0)t^2 \leq \varepsilon t^2$$

for all $|t|$ sufficiently small, whence

$$\frac{1}{2}\varphi''(0) \geq -\varepsilon.$$

Since $\varepsilon > 0$ was arbitrary, we conclude $\varphi''(0) = d^T f''(x^*) d \geq 0$. And since $d \in \mathbb{R}^n$ was arbitrary, we have shown $f''(x^*)$ to be positive semidefinite. \square

Theorem 3.3 (Second-order sufficient optimality condition).

Suppose that f is twice differentiable at x^* and

- (i) $f'(x^*) = 0$ and
- (ii) $f''(x^*)$ is positive definite², with minimal eigenvalue $\mu > 0$.

Then for every $\beta \in (0, \mu)$, there exists a neighborhood $U(x^*)$ of x^* such that

$$f(x) \geq f(x^*) + \frac{\beta}{2}\|x - x^*\|^2 \quad \text{for all } x \in U(x^*). \quad (3.1)$$

In particular, x^* is a strict local minimizer of f .

Proof. Here we use Theorem 2.3 directly for f (not along a curve). For every $\varepsilon > 0$, there exists $\delta > 0$ such that

$$\left| f(x^* + d) - f(x^*) - f'(x^*)d - \frac{1}{2}d^T f''(x^*)d \right| \leq \varepsilon \|d\|^2$$

holds for all $\|d\| < \delta$. According to the assumptions, $f'(x^*) = 0$ holds. Therefore,

$$-\varepsilon \|d\|^2 \leq f(x^* + d) - f(x^*) - \frac{1}{2}d^T f''(x^*)d$$

¹Due to the symmetry of $f''(x^*)$ this is equivalent to all eigenvalues of $f''(x^*)$ being non-negative.

²Due to the symmetry of $f''(x^*)$ this is equivalent to all eigenvalues of $f''(x^*)$ being positive.

holds for all $\|d\| < \delta$. This implies

$$f(x^* + d) \geq f(x^*) + \frac{1}{2} d^T f''(x^*) d - \varepsilon \|d\|^2$$

for all $\|d\| < \delta$.

From (2.12) (with $M = \text{Id}$), the values of the Rayleigh quotient associated with the symmetric matrix $f''(x^*)$ are bounded above and below by the extremal eigenvalues of $f''(x^*)$. In particular, we have

$$d^T f''(x^*) d \geq \mu \|d\|^2 \quad \text{for all } d \in \mathbb{R}^n.$$

We can now finalize the proof: for $\beta \in (0, \mu)$, choose $\varepsilon := (\mu - \beta)/2 > 0$ and an appropriate value of $\delta > 0$. Then we have

$$\begin{aligned} f(x^* + d) &\geq f(x^*) + \frac{1}{2} d^T f''(x^*) d - \varepsilon \|d\|^2 \\ &\geq f(x^*) + \frac{\mu}{2} \|d\|^2 - \varepsilon \|d\|^2 \\ &= f(x^*) + \frac{\beta}{2} \|d\|^2 \end{aligned}$$

for all $\|d\| < \delta$. □

Property (3.1) means that f has at least **quadratic growth** near x^* . Equivalently, f is locally strongly convex with parameter $\beta \in (0, \mu)$.

End of Week 1

§ 4 MINIMIZATION OF QUADRATIC FUNCTIONS

In this section we consider the simplest reasonable class of unconstrained optimization problems, namely the minimization of quadratic polynomials:

$$\text{Minimize } \phi(x) := \frac{1}{2} x^T A x - b^T x + c \quad \text{where } x \in \mathbb{R}^n. \quad (4.1)$$

The data of the problem is $A \in \mathbb{R}^{n \times n}$, $b \in \mathbb{R}^n$ and $c \in \mathbb{R}$. We can assume w.l.o.g. that A is symmetric.

Quiz 4.1: Why?

If we knew a spectral decomposition of $A = V \Lambda V^T$ (which of course we usually don't), we could represent the objective as $\phi(x) = \frac{1}{2} x^T V \Lambda V^T x - b^T V V^T x + c$. After a substitution of variables $x = V^T y$, this becomes $\tilde{\phi}(y) = \frac{1}{2} y^T \Lambda y - b^T V y + c$. Consequently, in these coordinates, the problem decomposes into a sum of n independent quadratic minimization problems in the components y_i .

Being able to solve (4.1) is an essential building block for subsequent tasks.

Lemma 4.1 (Solvability and global solutions of (4.1)³). Suppose that $A \in \mathbb{R}^{n \times n}$ is symmetric, $b \in \mathbb{R}^n$ and $c \in \mathbb{R}$. Then the following holds:

(i) If A is positive semidefinite, then the objective in (4.1) is convex. In this case, the following are equivalent:

- (a) The problem (4.1) possess at least one (global) minimizer.
- (b) The objective ϕ is bounded below.
- (c) $Ax = b$ is solvable.

The global minimizers of (4.1) are precisely the solutions of the linear system $Ax = b$.

(ii) In case A is not positive semidefinite⁴, the objective ϕ is not bounded below, thus problem (4.1) is unbounded.

Proof.

□

Corollary 4.2 (Unique solvability of (4.1)). Problem (4.1) possesses a unique (global) solution x^* if and only if A is s. p. d. In this case, $x^* = A^{-1}b$, and the optimal value is

$$\phi(x^*) = c - \frac{1}{2} \|x^*\|_A^2 = c - \frac{1}{2} \|A^{-1}b\|_A^2 = c - \frac{1}{2} \|b\|_{A^{-1}}^2.$$

We will assume for the remainder of § 4 that A is symmetric and positive definite (s. p. d.). Hence, the solution of (4.1) is equivalent to the solution of the linear system $Ax = b$. We denote that solution by $x^* = A^{-1}b$. Of course, we could be using a **direct solver**, such as **Gaussian elimination**, which computes an LU decomposition of A , or rather its s. p. d. variant without pivoting, which computes the **Cholesky decomposition** $A = LL^T$ with the lower triangular matrix L .⁵ However, when the problem is high-dimensional (such as $n \geq 10\,000$), then the generic $\sim n^3$ effort for solving the linear system becomes prohibitive. Even when A is sparse, as is often the case for high-dimensional problems, and a direct solver which exploits this is used⁶, this is no longer feasible for very high dimension n .

This is where **iterative solvers** for linear systems come into play. They do not solve the problem at once, but rather generate a sequence $(x^{(k)})$ which converges to the solution. Beyond the ability to deal with very high-dimensional problems, iterative solvers have another advantage: Any iterate $x^{(k)}$ of the method can be viewed as an approximate solution of $Ax = b$ (or an approximate solution of (4.1)), and we can stop the iteration as soon as the desired tolerance is reached, when the time budget is used up, or when something unexpected happens, e. g., A turns out not to be positive definite after all. Recall that direct solvers do not yield any usable approximate solutions of the system while they

³compare Nocedal, Wright, 2006, Lemma 4.7

⁴The matrix A possesses at least one negative eigenvalue.

⁵We assume you have seen these methods, e. g., in the class *Einführung in die Numerik*.

⁶such as a sparse Cholesky decomposition

are running; they have to carry through to the end, and only then return a solution, which is exact up to the influence of floating-point error. Iterative solvers have the additional advantage that they do not require access to the matrix A entry by entry. Rather they only require matrix-vector products, i. e., a function which evaluates $x \mapsto Ax$. **Quiz 4.2:** Can you think of an example where matrix-vector products are available, but you typically don't have access to the entries of the underlying matrix?

Our objective ϕ from (4.1) satisfies

$$\begin{aligned}\phi(x) &= \frac{1}{2}x^\top Ax - b^\top x + c \\ \nabla\phi(x) &= Ax - b =: r.\end{aligned}$$

We call $r = \nabla\phi(x)$ the **residual** of the linear system $Ax = b$ at x .⁷ Independently of any method we might be using to solve $Ax = b$ (or minimize ϕ), we have the following relation between the values of the objective, the **error** $x - x^*$ at a point x , and the residual at x :

Lemma 4.3. *We have*

$$\phi(x) - \phi(x^*) = \frac{1}{2}\|x - x^*\|_A^2 = \frac{1}{2}\|r\|_{A^{-1}}^2 = \frac{1}{2}\|\nabla\phi(x)\|_{A^{-1}}^2. \quad (4.2)$$

Proof. Direct calculation shows

$$\begin{aligned}\phi(x) - \phi(x^*) &= \frac{1}{2}x^\top Ax - b^\top x + c - \frac{1}{2}(x^*)^\top Ax^* + b^\top x^* - c \\ &= \frac{1}{2}x^\top Ax - (x^*)^\top Ax - \frac{1}{2}(x^*)^\top Ax^* + (x^*)^\top Ax^* \quad \text{since } b = Ax^* \\ &= \frac{1}{2}x^\top Ax - (x^*)^\top Ax + \frac{1}{2}(x^*)^\top Ax^* \\ &= \frac{1}{2}\|x - x^*\|_A^2 \\ &= \frac{1}{2}(x - x^*)^\top r = \frac{1}{2}r^\top A^{-1}r \quad \text{since } r = A(x - x^*) \\ &= \frac{1}{2}\|r\|_{A^{-1}}^2 \\ &= \frac{1}{2}\|\nabla\phi(x)\|_{A^{-1}}^2.\end{aligned}$$

□

We will discuss in the remainder of this section two different iterative methods for the solution of (4.1), and equivalently the solution of the linear system $Ax = b$, where A is s. p. d.⁸ These methods are the **gradient descent method** (also known as **steepest descent method**), and the **conjugate gradient method**.

⁷Sometimes the residual is defined in the literature with opposite sign. We do not write $r(x)$ to keep the notation concise. It will be clear from the context which vector x the residual is associated with.

⁸You can learn more about iterative solvers for more general linear systems (not related to optimization) in the class *Numerische lineare Algebra*.

We begin with the gradient descent method, which is based on the following simple

Idea: from the current iterate $x^{(k)}$, move a bit along the direction of steepest descent of the objective, and take the point reached as the next iterate $x^{(k+1)}$.

§ 4.1 DIRECTION OF STEEPEST DESCENT

We first need to clarify what **descent directions** and the **directions of steepest descent** of a function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ at a point x are.

Definition 4.4 (Descent direction).

*Suppose that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable at $x \in \mathbb{R}^n$. A vector $d \in \mathbb{R}^n$ is termed a **descent direction** for f at x if*

$$f'(x) d < 0. \quad (4.3)$$

holds.

By definition, the direction of steepest descent minimizes the directional derivative $f'(x) d$ over all vectors $d \in \mathbb{R}^n$ of constant length. What we mean by “length” is defined through the inner product M in use:

$$\begin{aligned} &\text{Minimize} && f'(x) d \quad \text{where } d \in \mathbb{R}^n \\ &\text{subject to} && \|d\|_M = 1. \end{aligned} \quad (4.4)$$

We note that we could be considering the equivalent problem

$$\begin{aligned} &\text{Minimize} && f'(x) d \quad \text{where } d \in \mathbb{R}^n \\ &\text{subject to} && \|d\|_M \leq 1. \end{aligned} \quad (4.5)$$

The normalization to unit length is, by the way, arbitrary.

Problems (4.4), (4.5) are constrained problems, but we can solve them without an elaborated theory. We rewrite the objective so that the directional derivative is expressed using the M -inner product⁹

$$f'(x) d = \nabla f(x)^\top d = \nabla f(x)^\top M^{-1} M d = (M^{-1} \nabla f(x))^\top M d,$$

where we used the symmetry of M (actually of M^{-1}) in the last step. The Cauchy-Schwarz inequality w.r.t. the M -inner product shows that this expression is minimal precisely when d is antiparallel to $M^{-1} \nabla f(x)$.

We summarize these findings:

Definition 4.5 (M -gradient, direction of steepest descent w.r.t. the M -inner product).

Suppose that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable at $x \in \mathbb{R}^n$ and that $f'(x) \neq 0$ holds.

⁹In case this means something to you, we determine the Riesz representer of $f'(x)$ w.r.t. the M -inner product.

(i) The vector

$$\nabla_M f(x) := M^{-1} \nabla f(x) \quad (4.6)$$

is termed the **gradient of f at x w.r.t. the M -inner product** or briefly: the **M -gradient**.

(ii) The vector $-\nabla_M f(x)$ and all of its positive multiples are termed the **directions of steepest descent of f at x w.r.t. the M -inner product**.

We evaluate the negative M -gradient (direction of steepest descent) by solving the linear system

$$M d^* = -\nabla f(x). \quad (4.7)$$

When using the Euclidean inner product ($M = \text{Id}$), we continue to write $\nabla f(x)$ instead of $\nabla_{\text{Id}} f(x)$. Sometimes, the use of $\nabla_M f(x)$ instead of the Euclidean gradient direction $\nabla f(x)$ is referred to as **preconditioning**.

§ 4.2 GRADIENT DESCENT METHOD WITH CAUCHY STEP SIZES

The direction of steepest descent at x used by the gradient method is thus¹⁰

$$d = -\nabla_M \phi(x) = -M^{-1} r.$$

Now that the choice of direction is clear, let us analyze the choice of the step size. We have the following expression for the difference of function values before and after a step:

$$\begin{aligned} \phi(x + \alpha d) - \phi(x) &= \frac{1}{2} (x + \alpha d)^T A (x + \alpha d) - b^T (x + \alpha d) + c - \frac{1}{2} x^T A x + b^T x - c \\ &= \frac{1}{2} (d^T A d) \alpha^2 + (A x - b)^T d \alpha \\ &= \frac{1}{2} (d^T A d) \alpha^2 + (r^T d) \alpha. \end{aligned} \quad (4.8)$$

Note: This formula holds for arbitrary directions d and step sizes α .

When $d \neq 0$, then the one-dimensional quadratic polynomial $\alpha \mapsto \phi(x + \alpha d)$ is strongly convex. It is therefore an obvious idea to choose α such that $\phi(x + \alpha d)$ is minimized. According to (4.8), we have

$$\begin{aligned} \frac{d}{d\alpha} \phi(x + \alpha d) &= (d^T A d) \alpha + r^T d, \\ \frac{d^2}{d\alpha^2} \phi(x + \alpha d) &= d^T A d > 0. \end{aligned}$$

Due to the positivity of the second derivative, the second-order sufficient condition (Theorem 3.3) is satisfied when $\frac{d}{d\alpha} \phi(x + \alpha d) = 0$, which amounts to

$$\alpha^* = -\frac{r^T d}{d^T A d}. \quad (4.9)$$

¹⁰We avoid iteration indices for now in order to avoid cluttered notation.

This “optimal” step size is also known as the **Cauchy step size**. For this choice, the difference of function values (4.8) before and after a step becomes

$$\begin{aligned}
 \phi(x + \alpha^* d) - \phi(x) &= \frac{1}{2} (d^T A d) (\alpha^*)^2 + (r^T d) \alpha^* \\
 &= \frac{1}{2} (d^T A d) \left(\frac{r^T d}{d^T A d} \right)^2 - (r^T d) \frac{r^T d}{d^T A d} \\
 &= -\frac{1}{2} \frac{(r^T d)^2}{d^T A d}.
 \end{aligned} \tag{4.10}$$

Note: This formula holds for arbitrary directions $d \neq 0$ but it uses the Cauchy step size α^* .

We can now state the steepest descent method w.r.t. the M -inner product and the Cauchy step size (4.9) for the iterative solution of the unconstrained quadratic minimization problem (4.1) with s. p. d. A . This method, with $M = \text{Id}$, was already published by [Cauchy, 1847](#).

Algorithm 4.6 (Gradient descent method for (4.1) w.r.t. the M -inner product with Cauchy step size).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: right-hand side $b \in \mathbb{R}^n$

Input: s. p. d. matrix A (or matrix-vector products with A)

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Output: approximate solution of (4.1), i. e., of $Ax = b$

```

1: Set  $k := 0$ 
2: Set  $r^{(0)} := Ax^{(0)} - b$  // evaluate the initial residual
3: Set  $d^{(0)} := -M^{-1}r^{(0)}$  // evaluate the initial negative  $M$ -gradient
4: Set  $\delta^{(0)} := -(r^{(0)})^T d^{(0)}$  //  $\delta^{(0)} = \|\nabla_M \phi(x^{(0)})\|_M^2 = \|r^{(0)}\|_{M^{-1}}^2$ 
5: while stopping criterion not met do
6:   Set  $q^{(k)} := A d^{(k)}$ 
7:   Set  $\theta^{(k)} := (q^{(k)})^T d^{(k)}$ 
8:   Set  $\alpha^{(k)} := \delta^{(k)} / \theta^{(k)}$  // evaluate the Cauchy step size
9:   Set  $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$  // update the iterate
10:  Set  $r^{(k+1)} := r^{(k)} + \alpha^{(k)} q^{(k)}$  // update the residual
11:  Set  $d^{(k+1)} := -M^{-1}r^{(k+1)}$  // evaluate the negative  $M$ -gradient
12:  Set  $\delta^{(k+1)} := -(r^{(k+1)})^T d^{(k+1)}$  //  $\delta^{(k+1)} = \|\nabla_M \phi(x^{(k+1)})\|_M^2 = \|r^{(k+1)}\|_{M^{-1}}^2$ 
13:  Set  $k := k + 1$ 
14: end while
15: return  $x^{(k)}$ 

```

The following can be said about [Algorithm 4.6](#).

Remark 4.7 (on [Algorithm 4.6](#)).

(i) [Algorithm 4.6](#) is an iterative solver for the unconstrained quadratic minimization problem (4.1) with s. p. d. A , and simultaneously an iterative solver for the linear system $Ax = b$.

(ii) We do not require access to the matrix A entry by entry, matrix-vector products with A are enough.

- (iii) The user gets to choose the inner product M . This is known as **preconditioning**, and therefore **Algorithm 4.6** is often termed a **preconditioned gradient descent method**. The case $M = \text{Id}$ corresponds to the classical gradient descent method (without preconditioning).
- (iv) We also do not require access to the inner product matrix M entry by entry, matrix-vector products with M^{-1} (i. e., solutions of linear systems with M) are enough.
- (v) **Algorithm 4.6** requires the storage of four vectors, which are iteratively overwritten: iterates $x^{(k)}$, residuals $r^{(k)}$, negative gradient directions $d^{(k)}$, and vectors $q^{(k)} = A d^{(k)}$.
- (vi) Every iteration requires one matrix-vector product with A and one application of the preconditioner, i. e., one matrix-vector product with M^{-1} .
- (vii) In order to mitigate the accumulation of round-off error, it is advisable to evaluate the residual every, say, 50 iterations according to $r^{(k)} := A x^{(k)} - b$, rather than update it.
- (viii) The Cauchy step sizes satisfy

$$0 < \lambda_{\min}(A; M) \leq \frac{1}{\alpha^{(k)}} = \frac{(d^{(k)})^\top A d^{(k)}}{(d^{(k)})^\top M d^{(k)}} \leq \lambda_{\max}(A; M), \quad (4.11)$$

as long as $d^{(k)} \neq 0$ holds, i. e., as long as $x^{(k)} \neq x^*$. Consequently, the Cauchy step sizes generated can be used to obtain estimates on the eigenvalues of A w.r.t. M .

- (ix) When **Algorithm 4.6** is provided with the value of c , the following recursion can be added to the algorithm to keep track of the value of the objective:

$$\phi(x^{(0)}) = c + \frac{1}{2}(r^{(0)} - b)^\top (x^{(0)}) \quad \text{initialization} \quad (4.12a)$$

$$\phi(x^{(k+1)}) = \phi(x^{(k)}) - \frac{1}{2} \alpha^{(k)} \delta^{(k)} \quad \text{update.} \quad (4.12b)$$

This does not incur noticeable computational overhead and does not require the storage of extra vectors. Alternatively, the value of $\phi(x^{(0)})$ can be provided.

We now seek to estimate the speed of convergence of **Algorithm 4.6**. The function values at the iterates satisfy

$$\begin{aligned} & \phi(x^{(k+1)}) - \phi(x^*) \\ &= \frac{1}{2} \|r^{(k+1)}\|_{A^{-1}}^2 \quad \text{by (4.2)} \\ &= \frac{1}{2} \|r^{(k)} + \alpha^{(k)} A d^{(k)}\|_{A^{-1}}^2 \\ &= \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 + \alpha^{(k)} (r^{(k)})^\top d^{(k)} + \frac{1}{2} [\alpha^{(k)}]^2 (d^{(k)})^\top A d^{(k)}. \end{aligned}$$

This formula so far holds for any choice of step size $\alpha^{(k)}$ and any choice of direction $d^{(k)}$. We now insert the Cauchy step size $\alpha^{(k)} = -\frac{(r^{(k)})^\top d^{(k)}}{(d^{(k)})^\top A d^{(k)}}$ and obtain

$$\begin{aligned} &= \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 - \frac{[(r^{(k)})^\top d^{(k)}]^2}{(d^{(k)})^\top A d^{(k)}} + \frac{1}{2} \frac{[(r^{(k)})^\top d^{(k)}]^2}{(d^{(k)})^\top A d^{(k)}} \\ &= \left(1 - \frac{[(r^{(k)})^\top d^{(k)}]^2}{[(d^{(k)})^\top A d^{(k)}] [(r^{(k)})^\top A^{-1} r^{(k)}]}\right) (\phi(x^{(k)}) - \phi(x^*)) \quad \text{by (4.2).} \end{aligned}$$

The directions $d^{(k)}$ are still arbitrary. Inserting the relationship $d^{(k)} = -M^{-1} r^{(k)} = -\nabla_M \phi(x^{(k)})$ characteristic for gradient descent, in the form $r^{(k)} = -M d^{(k)}$, we obtain

$$= \left(1 - \frac{[(d^{(k)})^\top M d^{(k)}]^2}{[(d^{(k)})^\top A d^{(k)}] [(d^{(k)})^\top M A^{-1} M d^{(k)}]}\right) (\phi(x^{(k)}) - \phi(x^*)).$$

The fraction is precisely the type of expression estimated by the generalized Kantorovich inequality (2.19). This yields

$$\begin{aligned} &\phi(x^{(k+1)}) - \phi(x^*) \\ &\leq \left(1 - \frac{4\alpha\beta}{(\alpha+\beta)^2}\right) (\phi(x^{(k)}) - \phi(x^*)) \\ &= \left(\frac{\beta-\alpha}{\beta+\alpha}\right)^2 (\phi(x^{(k)}) - \phi(x^*)) \\ &= \left(\frac{\kappa-1}{\kappa+1}\right)^2 (\phi(x^{(k)}) - \phi(x^*)) \quad \text{since } \kappa = \beta/\alpha. \end{aligned}$$

We have thus shown the following classical convergence result for [Algorithm 4.6](#):

Theorem 4.8 (Convergence of [Algorithm 4.6](#)). *Suppose that $A \in \mathbb{R}^{n \times n}$ and M are both s. p. d., $\alpha := \lambda_{\min}(A; M)$ and $\beta := \lambda_{\max}(A; M)$ are the extremal generalized eigenvalues of A w.r.t. M . Then for any choice of the initial guess $x^{(0)}$, the gradient descent method with Cauchy step sizes converges to the unique solution $x^* = A^{-1}b$ of (4.1). In terms of the generalized condition number $\kappa = \beta/\alpha$, we have the estimates*

$$\phi(x^{(k+1)}) - \phi(x^*) \leq \left(\frac{\kappa-1}{\kappa+1}\right)^2 (\phi(x^{(k)}) - \phi(x^*)) \quad (4.13a)$$

$$\|x^{(k+1)} - x^*\|_A \leq \left(\frac{\kappa-1}{\kappa+1}\right) \|x^{(k)} - x^*\|_A \quad (4.13b)$$

and consequently

$$\phi(x^{(k)}) - \phi(x^*) \leq \left(\frac{\kappa-1}{\kappa+1}\right)^{2k} (\phi(x^{(0)}) - \phi(x^*)) \quad (4.13c)$$

$$\|x^{(k)} - x^*\|_A \leq \left(\frac{\kappa-1}{\kappa+1}\right)^k \|x^{(0)} - x^*\|_A. \quad (4.13d)$$

Moreover, the objective values $\phi(x^{(k)})$ and thus the norm of the error $\|x^{(k)} - x^*\|_A$ are monotonically decreasing.

As an immediate consequence of this theorem, we can estimate the maximal number of iterations required until the left-hand terms in (4.13c) and (4.13d) have been decreased relative to their initial values.

Corollary 4.9 (Maximal number of iterations required in Algorithm 4.6). *Given positive numbers ε_1 and ε_2 , it takes*

$$k \leq \left\lceil \frac{\kappa}{4} \ln \left(\frac{1}{\varepsilon_1} \right) \right\rceil \text{ iterations until } \left(\frac{\kappa-1}{\kappa+1} \right)^{2k} \leq \varepsilon_1,$$

$$k \leq \left\lceil \frac{\kappa}{2} \ln \left(\frac{1}{\varepsilon_2} \right) \right\rceil \text{ iterations until } \left(\frac{\kappa-1}{\kappa+1} \right)^k \leq \varepsilon_2.$$

Proof. (1) We first show that

$$-\ln \left(\frac{\kappa-1}{\kappa+1} \right) \geq \frac{2}{\kappa} > 0$$

holds for all $\kappa \geq 1$. At $\kappa = \frac{e+1}{e-1}$, we have

$$-\ln \left(\frac{\kappa-1}{\kappa+1} \right) = -\ln \left(\frac{1}{e} \right) = 1 > \frac{2}{\kappa} = 2 \frac{e-1}{e+1} \approx 0.92.$$

We now show that

$$\frac{d}{d\kappa} \left[-\ln \left(\frac{\kappa-1}{\kappa+1} \right) \right] \geq \frac{d}{d\kappa} \frac{2}{\kappa}$$

holds for all $\kappa > 1$, which proves the claim. The derivative on the left is $\frac{-2}{(\kappa-1)(\kappa+1)}$, while the derivative on the right is $\frac{-2}{\kappa^2}$. In view of $0 < \kappa^2 - 1 < \kappa^2$ for all $\kappa > 1$, we conclude

$$\frac{-2}{(\kappa-1)(\kappa+1)} < \frac{-2}{\kappa^2} < 0 \quad \text{for all } \kappa > 1.$$

(2) Taking the reciprocal of the inequality shown above, we obtain

$$0 < \frac{-1}{\ln \left(\frac{\kappa-1}{\kappa+1} \right)} \leq \frac{\kappa}{2} \quad (*)$$

for all $\kappa > 1$.

(3) Given $\kappa > 1$, we easily infer that $\left(\frac{\kappa-1}{\kappa+1} \right)^{2k} \leq \varepsilon_1$ holds if and only if

$$k \geq \frac{1}{2} \frac{-\ln \varepsilon_1}{-\ln \left(\frac{\kappa-1}{\kappa+1} \right)} = \frac{1}{2} \frac{-1}{\ln \left(\frac{\kappa-1}{\kappa+1} \right)} \ln \left(\frac{1}{\varepsilon_1} \right). \quad (**)$$

In view of the inequality (*) shown above, we obtain that

$$k \geq \left\lceil \frac{\kappa}{4} \ln \left(\frac{1}{\varepsilon_1} \right) \right\rceil \geq \frac{\kappa}{4} \ln \left(\frac{1}{\varepsilon_1} \right)$$

implies (**), which proves the first claim.

The second claim follows similarly. □

Remark 4.10 (on [Theorem 4.8](#)).

- (i) [\(4.13b\)](#) shows the Q -linear convergence of $(x^{(k)})$ to the solution x^* in the A -norm.
- (ii) The contraction factor is $0 \leq \frac{\kappa-1}{\kappa+1} < 1$, i. e., the convergence estimate depends on the ratio κ between the largest and the smallest generalized eigenvalue of A w.r.t. M . It is the purpose of the preconditioner/inner product M to keep this ratio small.
- (iii) In the extreme case $\kappa = 1$ we obtain convergence in one step. This happens precisely when M is a multiple of A . However, we need to solve a linear system with M in every iteration. If we were able to do that, we might as well solve $Ax = b$ directly.
- (iv) A good preconditioner is a compromise between a moderate generalized condition number κ and the effort in applying M^{-1} . Finding a good preconditioner generally requires knowledge about the problem at hand.
- (v) It is natural to measure convergence of the method in the A -norm of the error because, due to [\(4.2\)](#), that is the quantity being minimized.
- (vi) The estimates of [Theorem 4.8](#) are worst-case estimates since they do not depend on the initial guess $x^{(0)}$. In fact, as can be seen in [Figure 4.1c](#), the actual contraction factor for the objective values can be significantly smaller for some initial guesses than the estimate [\(4.13c\)](#) suggests.

[Figure 4.1](#) illustrates the convergence behavior of [Algorithm 4.6](#) for a 2-dimensional example problem from a number of different initial guesses $x^{(0)}$. We observe the typical “zig-zagging” behavior of the iterates as they converge to the solution. This happens for any initial guess, except when $x^{(0)} - x^*$ happens to be a generalized eigenvector of A w.r.t. M , in which case convergence occurs in one step due to $x^{(1)} = x^*$. (Such a case is not shown in [Figure 4.1](#)). **Quiz 4.3:** Suppose A , b and M are given and you consider a random distribution of initial values $x^{(0)}$ in \mathbb{R}^n , which has a probability density. What is the probability of hitting an initial value such that convergence happens in one step?

The zig-zagging behavior of the iterates $x^{(k)}$, as well as the non-monotone behavior of $\|r^{(k)}\|_{M^{-1}}$ have been analyzed in detail in the literature; see for instance [Akaike, 1959](#); [Forsythe, 1968](#); [Nocedal, Sartenaer, Zhu, 2002](#). Essentially what happens is that, asymptotically, the error $x^{(k)} - x^*$ alternates between elements of the eigenspaces belonging to the smallest and the largest eigenvalues of A w.r.t. M . This is ultimately a consequence of the fact that gradient descent is a memoryless method.

It has also been shown that a necessary condition in order for the norm of the gradient $\|r^{(k)}\|_{M^{-1}}$ to converge non-monotonically is that the condition number satisfy $\kappa > 3 + 2\sqrt{2} \approx 5.83$.

It remains to discuss stopping criteria. Several quantities may be of interest in this respect:

- (i) Are we happy with a point $x^{(k)}$ which is almost stationary, i. e., where $\|r^{(k)}\|_{M^{-1}}$ is small?
- (ii) Are we happy with a point $x^{(k)}$ whose objective value is near the optimal value, i. e., where $\phi(x^{(k)}) - \phi(x^*)$ is small, or equivalently, where $\|x^{(k)} - x^*\|_A$ is small?

(a) Iterates $(x^{(k)})$ of the method. Each color corresponds to a different initial guess $x^{(0)}$.

(b) The norm of the gradient $\sqrt{\delta^{(k)}} = \|\nabla_M \phi(x^{(k)})\|_M = \|r^{(k)}\|_{M^{-1}}$ does not necessarily converge monotonically.

(c) The objective values $\phi(x^{(k)}) - \phi(x^*)$ converge monotonically. The black line illustrates the bound (4.13c).

Figure 4.1: Illustration of the convergence behavior of Algorithm 4.6 from a number of initial guesses $x^{(0)}$. No preconditioning ($M = \text{Id}$) is used. The two eigenvalues of the matrix are $\alpha = 1$ and $\beta = 10$ so the condition number is $\kappa = 10$.

- (iii) Are we happy with a point $x^{(k)}$ whose distance from the minimizer is small in the preconditioner-induced norm M , i. e., where $\|x^{(k)} - x^*\|_M$ is small?

The only of these three quantities which we can evaluate without knowing x^* or $\phi(x^*)$ is $\delta^{(k)} = \|r^{(k)}\|_{M^{-1}}^2$. Therefore, many implementations use one of the following combinations of a relative and an absolute criterion based on $\|r^{(k)}\|_{M^{-1}}$:

$$\|r^{(k)}\|_{M^{-1}} \leq \varepsilon_{\text{rel}} \|r^{(0)}\|_{M^{-1}}, \quad \text{i. e., } \delta^{(k)} \leq \varepsilon_{\text{rel}}^2 \delta^{(0)}, \quad (4.14a)$$

$$\|r^{(k)}\|_{M^{-1}} \leq \varepsilon_{\text{abs}}, \quad \text{i. e., } \delta^{(k)} \leq \varepsilon_{\text{abs}}^2, \quad (4.14b)$$

$$\|r^{(k)}\|_{M^{-1}} \leq \varepsilon_{\text{rel}} \|r^{(0)}\|_{M^{-1}} + \varepsilon_{\text{abs}}, \quad \text{i. e., } (\delta^{(k)})^{1/2} \leq \varepsilon_{\text{rel}} (\delta^{(0)})^{1/2} + \varepsilon_{\text{abs}}, \quad (4.14c)$$

$$\|r^{(k)}\|_{M^{-1}} \leq \max\{\varepsilon_{\text{rel}} \|r^{(0)}\|_{M^{-1}}, \varepsilon_{\text{abs}}\}, \quad \text{i. e., } \delta^{(k)} \leq \max\{\varepsilon_{\text{rel}}^2 \delta^{(0)}, \varepsilon_{\text{abs}}^2\}. \quad (4.14d)$$

Let us see which consequences either of the implementable stopping criteria (4.14) has on the other two quantities of interest:

Lemma 4.11 (Implications). *The criteria from (4.14) imply, respectively,*

$$\left. \begin{aligned} \|x^{(k)} - x^*\|_A &\leq \sqrt{\kappa} \varepsilon_{\text{rel}} \|x^{(0)} - x^*\|_A \\ \|x^{(k)} - x^*\|_M &\leq \kappa \varepsilon_{\text{rel}} \|x^{(0)} - x^*\|_M \end{aligned} \right\} \quad (4.15a)$$

$$\left. \begin{aligned} \|x^{(k)} - x^*\|_A &\leq (1/\sqrt{\alpha}) \varepsilon_{\text{abs}} \\ \|x^{(k)} - x^*\|_M &\leq (1/\alpha) \varepsilon_{\text{abs}} \end{aligned} \right\} \quad (4.15b)$$

$$\left. \begin{aligned} \|x^{(k)} - x^*\|_A &\leq \sqrt{\kappa} \varepsilon_{\text{rel}} \|x^{(0)} - x^*\|_A + (1/\sqrt{\alpha}) \varepsilon_{\text{abs}} \\ \|x^{(k)} - x^*\|_M &\leq \kappa \varepsilon_{\text{rel}} \|x^{(0)} - x^*\|_M + (1/\alpha) \varepsilon_{\text{abs}} \end{aligned} \right\} \quad (4.15c)$$

$$\left. \begin{aligned} \|x^{(k)} - x^*\|_A &\leq \max\{\sqrt{\kappa} \varepsilon_{\text{rel}} \|x^{(0)} - x^*\|_A, (1/\sqrt{\alpha}) \varepsilon_{\text{abs}}\} \\ \|x^{(k)} - x^*\|_M &\leq \max\{\kappa \varepsilon_{\text{rel}} \|x^{(0)} - x^*\|_M, (1/\alpha) \varepsilon_{\text{abs}}\} \end{aligned} \right\} \quad (4.15d)$$

Proof. homework problem 2.3 □

§ 4.3 GRADIENT DESCENT METHOD WITH CONSTANT STEP SIZES

We can show that the gradient descent method continues to converge Q-linearly when, in place of the Cauchy step sizes, we choose constant step sizes $\alpha^{(k)} \equiv \bar{\alpha}$ within a certain range. We obtain as above

$$\begin{aligned} \phi(x^{(k+1)}) - \phi(x^*) &= \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 + \bar{\alpha} (r^{(k)})^\top d^{(k)} + \frac{1}{2} \bar{\alpha}^2 (d^{(k)})^\top A d^{(k)}. \end{aligned}$$

We leave $\bar{\alpha}$ open for now and insert the gradient descent relation $r^{(k)} = -M d^{(k)}$ to obtain

$$\begin{aligned} &= \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 - \bar{\alpha} (d^{(k)})^\top M d^{(k)} + \frac{1}{2} \bar{\alpha}^2 (d^{(k)})^\top A d^{(k)} \\ &\leq \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 - \bar{\alpha} (d^{(k)})^\top M d^{(k)} + \frac{1}{2} \bar{\alpha}^2 \beta (d^{(k)})^\top M d^{(k)} \quad \text{since } d^\top A d \leq \beta d^\top M d \\ &= \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 + \bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right) (d^{(k)})^\top M d^{(k)}. \end{aligned}$$

Here we need to convert the last term into $d^\top M A^{-1} M d$, which is equal to $r^\top A^{-1} r$, so that it can be combined with the first term. We require that the coefficient $\bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right)$ is negative to obtain convergence. Consequently, we use the first estimate in (2.15a):

$$\begin{aligned} &\leq \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 + \bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right) \alpha (d^{(k)})^\top M A^{-1} M d^{(k)} \quad \text{provided that } \bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right) < 0 \\ &= \left[1 + 2 \bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right) \alpha \right] \frac{1}{2} \|r^{(k)}\|_{A^{-1}}^2 \\ &= \left[1 + 2 \bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right) \alpha \right] (\phi(x^{(k)}) - \phi(x^*)). \end{aligned}$$

The condition that $\bar{\alpha} \left(\frac{1}{2} \bar{\alpha} \beta - 1 \right)$ is negative amounts to $\bar{\alpha} \in (0, \frac{2}{\beta})$. It is precisely the midpoint $\bar{\alpha} = 1/\beta$ of this interval which minimizes this term and yields the optimal estimate, and the expression in $[\dots]$ becomes $\frac{\kappa-1}{\kappa}$ in this case.

Remark 4.12 (on the convergence of Algorithm 4.6 with constant step sizes).

- (i) We have shown that Algorithm 4.6, where Line 8 is replaced by $\alpha^{(k)} := \bar{\alpha}$, still converges, provided that $\bar{\alpha} \in (0, \frac{2}{\beta})$.
- (ii) From a practical perspective, we therefore need to know at least an upper bound for the largest eigenvalue β of the generalized eigenvalue problem $Ax = \lambda Mx$. When we have $\beta \leq \beta_{\text{estimate}}$ and choose $\bar{\alpha} \in (0, \frac{2}{\beta_{\text{estimate}}})$, we also have $\bar{\alpha} \in (0, \frac{2}{\beta})$.
- (iii) The choice $\bar{\alpha} = \frac{1}{\beta}$ yields the optimal estimate. In this case, we obtain

$$\phi(x^{(k+1)}) - \phi(x^*) \leq \left(\frac{\kappa-1}{\kappa} \right) (\phi(x^{(k)}) - \phi(x^*)).$$

Since for all $\kappa \geq 1$, we have $\left(\frac{\kappa-1}{\kappa+1} \right)^2 \leq \frac{\kappa-1}{\kappa}$, the contraction factor in the bound we obtained with constant step sizes is worse than the one for the Cauchy step sizes; see (4.13a). Consequently, there is no reason to prefer the gradient descent method with constant step sizes over the version with Cauchy step sizes.

- (iv) The Kantorovich inequality was not needed in the proof.

Figure 4.2 illustrates the convergence behavior of Algorithm 4.6 with constant step sizes for a 2-dimensional example problem from a number of different initial guesses $x^{(0)}$.

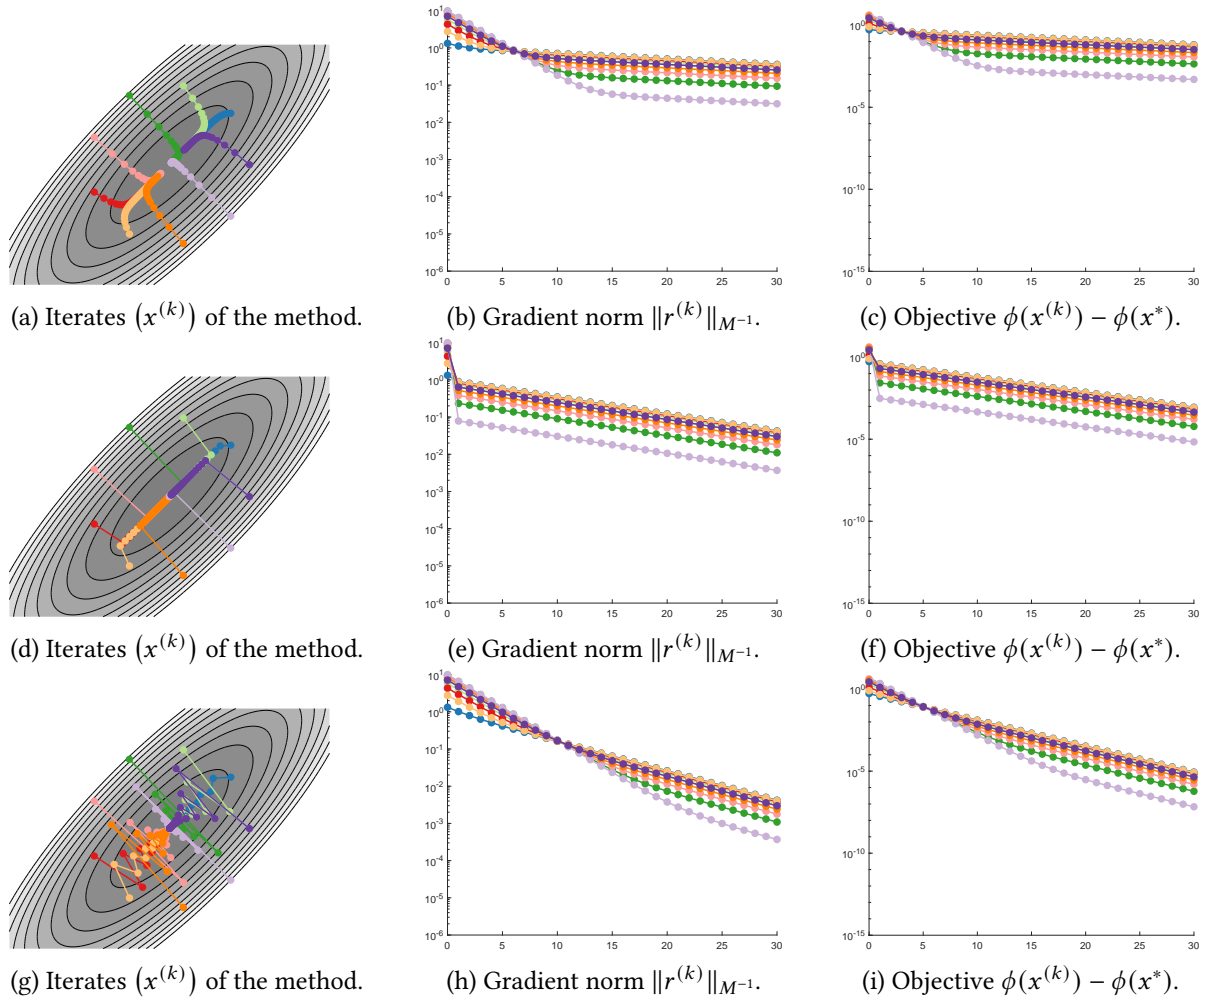

Figure 4.2: Illustration of the convergence behavior of Algorithm 4.6 with various constant step sizes instead of the Cauchy step size. The step sizes, from top to bottom, are $\bar{\alpha} \in \{0.03, 0.10, 0.17\}$. No preconditioning ($M = \text{Id}$) is used. The two eigenvalues of the matrix are $\alpha = 1$ and $\beta = 10$ so the admissible range of constant step sizes is $\bar{\alpha} \in (0, \frac{2}{\beta}) = (0, 0.2)$.

§ 4.4 GRADIENT DESCENT METHOD WITH OTHER STEP SIZE RULES

Step size rules other than the Cauchy step sizes and constant step sizes have been proposed and analyzed in the literature with the goal of breaking the non-efficient zig-zagging pattern; among them Barzilai, Borwein, 1988; De Asmundis, di Serafino, Riccio, et al., 2013; De Asmundis, di Serafino, Hager, et al., 2014; Gonzaga, Schneider, 2015. We do not go into the details here but mention one remarkable result from Gonzaga, 2016, Theorem 1. Suppose that $\alpha := \lambda_{\min}(A; M)$ and $\beta := \lambda_{\max}(A; M)$ are the extremal generalized eigenvalues of A w.r.t. M , and $\kappa := \frac{\beta}{\alpha}$ is the generalized condition number. Suppose that $\kappa \geq 1.06$ and that

$$k := \left\lceil \sqrt{\kappa} \ln \left(\frac{2}{\varepsilon_1} \right) \right\rceil.$$

holds. Consider the set of mutually distinct, **precomputed** step sizes

$$\left\{ \alpha^{(j)} := \frac{1}{\omega^{(j)}} \mid \omega^{(j)} := \frac{\beta - \alpha}{2} \cos \left(\frac{1 + 2j}{2k} \pi \right) + \frac{\beta + \alpha}{2}, j = 0, 1, \dots, k-1 \right\}.$$

Then the gradient descent method Algorithm 4.6 with step sizes $\alpha^{(k)}$, applied **in any order**, requires at most

$$k \text{ iterations until } \left(\frac{\kappa - 1}{\kappa + 1} \right)^{2k} \leq \varepsilon_1.$$

The interesting fact is that, compared to the estimate of Corollary 4.9 for the Cauchy step size, the bound on the iteration numbers is proportional only to $\sqrt{\kappa}$, not to κ . The result can be modified so that it is not required to know the extremal eigenvalues exactly, but knowledge of an interval containing them is sufficient.

We are going to obtain a similar complexity result for the conjgate gradient method in § 4.6.

§ 4.5 GRADIENT DESCENT METHOD AS DISCRETIZED GRADIENT FLOW

We conclude the discussion of the gradient descent method by interpreting it in another way. Consider the differential equation

$$\begin{aligned} \dot{x}(t) &= -\nabla_M f(x(t)), \quad t \geq 0 \\ x(0) &= x^{(0)}. \end{aligned} \tag{4.16}$$

This is known as the **gradient flow** associated with f . Its stationary points are precisely the stationary points of f . Due to

$$\frac{d}{dt} f(x(t)) = f'(x(t)) \dot{x}(t) = -f'(x(t)) M^{-1} \nabla f(x(t)) = -\|\nabla f(x(t))\|_{M^{-1}}^2 = -\|\nabla_M f(x(t))\|_M^2, \tag{4.17}$$

the value of f is decreasing along the path $x(t)$.

When we discretize (4.16) by the explicit (forward) Euler method with time step size $\Delta t^{(k)}$, we obtain

$$\frac{x^{(k+1)} - x^{(k)}}{\Delta t^{(k)}} = -M^{-1} \nabla f(x^{(k)}),$$

or equivalently,

$$x^{(k+1)} = x^{(k)} - \Delta t^{(k)} M^{-1} \nabla f(x^{(k)}). \quad (4.18)$$

This is precisely a step of the gradient descent method with step size $\Delta t^{(k)}$. Therefore, we can interpret the gradient descent method as a discretization of the continuous gradient flow equation.

End of Week 2

§ 4.6 CONJUGATE GRADIENT METHOD

The typical inefficient zig-zagging pattern of the directions $d^{(k)}$ is a consequence of the fact that gradient descent is a memoryless method. That is, we could restart the method at any iterate and it would produce the same iterates, whether restarted or not. This is where the **conjugate gradient method** (**CG method**, introduced in [Hestenes, Stiefel, 1952](#)) takes a different turn. It works with search directions $d^{(k)}$ which are pairwise A -orthogonal (also known as A -conjugate), and builds a memory of previously visited directions.

Definition 4.13 (Conjugate directions). *Suppose that $A \in \mathbb{R}^{n \times n}$ is s. p. d. A set of non-zero vectors $\{d^{(0)}, \dots, d^{(k)}\} \subset \mathbb{R}^n$ is termed **A -conjugate** if*

$$(d^{(i)})^\top A d^{(j)} = 0 \quad \text{for } 0 \leq i, j \leq k, \quad i \neq j.$$

In other words, A -conjugate vectors are pairwise orthogonal w.r.t. the A -inner product. In particular, $\{d^{(0)}, \dots, d^{(k)}\}$ is a linearly independent set. (**Quiz 4.4:** Can you prove that?)

The CG method is a member of the class of **conjugate direction methods**. We begin by describing the properties of a generic conjugate direction method first before we particularize to the CG method. A conjugate direction method chooses its search directions $d^{(0)}, d^{(1)}, \dots$ so that they are A -conjugate, and the iterates satisfy

$$x^{(k+1)} = x^{(k)} + \alpha^{(k)} d^{(k)}. \quad (4.19)$$

The step size $\alpha^{(k)}$ is the Cauchy step size, which minimizes the one-dimensional quadratic polynomial

$$\alpha \mapsto \phi(x^{(k)} + \alpha d^{(k)}).$$

That is, we have

$$\alpha^{(k)} := -\frac{(r^{(k)})^\top d^{(k)}}{(d^{(k)})^\top A d^{(k)}}, \quad (4.20)$$

compare (4.9). As in the gradient descent method, the residuals satisfy the recursion

$$r^{(k+1)} = r^{(k)} + \alpha^{(k)} A d^{(k)}. \quad (4.21)$$

Conjugate direction methods have the remarkable property that the sequence of one-dimensional minimizations in the A -conjugate directions $d^{(0)}, d^{(1)}, \dots$ is equivalent to the minimization over the entire affine subspace $x^{(0)} + \text{span}\{d^{(0)}, d^{(1)}, \dots\}$. This is shown in the following result.

Lemma 4.14 (Properties of conjugate direction methods). *Suppose that $A \in \mathbb{R}^{n \times n}$ is s. p. d. Given an initial guess $x^{(0)}$ and a set $\{d^{(0)}, d^{(1)}, \dots, d^{(k-1)}\}$, $k \geq 1$ of A -conjugate search directions, suppose that the iterates $x^{(0)}, \dots, x^{(k)}$ are generated according to (4.19) with Cauchy step size (4.20). Then the following holds.*

$$(i) \quad (r^{(k)})^\top d^{(i)} = 0 \quad \text{for all } i = 0, 1, \dots, k-1. \quad (4.22)$$

(ii) $x^{(k)}$ minimizes ϕ over the affine subspace $x^{(0)} + \text{span}\{d^{(0)}, d^{(1)}, \dots, d^{(k-1)}\}$.

Proof. We can show **Statement (i)** via induction over k . For $k = 1$,

$$\begin{aligned} (r^{(1)})^\top d^{(0)} &= (Ax^{(1)} - b)^\top d^{(0)} && \text{by definition of the residual} \\ &= (Ax^{(0)} + \alpha^{(0)}Ad^{(0)} - b)^\top d^{(0)} && \text{by (4.19)} \\ &= (r^{(0)})^\top d^{(0)} + \alpha^{(0)}(d^{(0)})^\top Ad^{(0)} && \text{by definition of the residual} \\ &= 0 && \text{since } \alpha^{(0)} \text{ is the Cauchy step size (4.20).} \end{aligned}$$

The induction step assumes $(r^{(k-1)})^\top d^{(i)} = 0$ for all $i = 0, 1, \dots, k-2$ and proceeds as follows.

$$\begin{aligned} (r^{(k)})^\top d^{(k-1)} &= (r^{(k-1)} + \alpha^{(k-1)}Ad^{(k-1)})^\top d^{(k-1)} && \text{by the residual recursion (4.21)} \\ &= 0 && \text{since } \alpha^{(k-1)} \text{ is the Cauchy step size (4.20).} \end{aligned}$$

For the remaining search directions $d^{(i)}$, $i = 0, 1, \dots, k-2$ we have

$$\begin{aligned} (r^{(k)})^\top d^{(i)} &= (r^{(k-1)} + \alpha^{(k-1)}Ad^{(k-1)})^\top d^{(i)} && \text{by the residual recursion (4.21)} \\ &= \underbrace{(r^{(k-1)})^\top d^{(i)}}_{=0 \text{ by assumption}} + \underbrace{\alpha^{(k-1)}(d^{(k-1)})^\top Ad^{(i)}}_{=0 \text{ due to } A\text{-conjugacy}} \\ &= 0. \end{aligned}$$

For **Statement (ii)** we consider the function $h: \mathbb{R}^k \rightarrow \mathbb{R}$

$$h(\sigma) := \phi\left(x^{(0)} + \sum_{j=0}^{k-1} \sigma_j d^{(j)}\right).$$

h is strongly convex (**Quiz 4.5:** Why?), and the unique minimizer σ^* is characterized by

$$\frac{\partial h(\sigma^*)}{\partial \sigma_i} = \nabla \phi\left(x^{(0)} + \sum_{j=0}^{k-1} \sigma_j^* d^{(j)}\right)^\top d^{(i)} = 0, \quad i = 0, \dots, k-1. \quad (*)$$

However, we already know that it is the iterate

$$x^{(k)} = x^{(0)} + \sum_{j=0}^{k-1} \alpha^{(j)} d^{(j)} \in x^{(0)} + \text{span}\{d^{(0)}, d^{(1)}, \dots, d^{(k-1)}\}$$

which satisfies (*), since

$$\nabla \phi \left(x^{(0)} + \sum_{j=0}^{k-1} \alpha^{(j)} d^{(j)} \right)^\top d^{(i)} = \nabla \phi(x^{(k)})^\top d^{(i)} = (r^{(k)})^\top d^{(i)} = 0$$

holds for all $i = 0, \dots, k-1$, as shown in [Statement \(i\)](#). \square

Corollary 4.15 (Properties of conjugate direction methods). *Any iterative method (4.19) using A -conjugate directions $d^{(k)}$ and Cauchy step sizes (4.20) converges to the unique solution of (4.1) in at most n steps.*

Proof. The search directions $d^{(k)}$ are A -conjugate and thus linearly independent. Therefore,

$$\text{span}\{d^{(0)}, d^{(1)}, \dots, d^{(n-1)}\}$$

is all of \mathbb{R}^n , so that $x^{(n)}$ minimizes ϕ over all of \mathbb{R}^n by [Lemma 4.14](#). \square

In practice, the statement of [Corollary 4.15](#) is weakened by floating point error. Moreover, the result of [Corollary 4.15](#) is not really relevant for high-dimensional problems since performing n iterations is prohibitively expensive. We will later see more practical converge estimates.

There are many possibilities to generate pairwise A -conjugate directions $d^{(k)}$, each of which leads to a different conjugate direction method. The **conjugate gradient method (CG method)** determines the current direction $d^{(k)}$ as a linear combination of the previous direction $d^{(k-1)}$ and the current steepest descent direction $-M^{-1}r^{(k)}$.¹¹

$$\begin{aligned} d^{(0)} &:= -M^{-1}r^{(0)} && \text{for } k = 0, \\ d^{(k)} &:= -M^{-1}r^{(k)} + \beta^{(k)} d^{(k-1)} && \text{for } k \geq 1. \end{aligned} \quad (4.23)$$

The coefficient $\beta^{(k)}$ is determined in such a way that at least $d^{(k)}$ and $d^{(k-1)}$ are A -conjugate:

$$\beta^{(k)} := \frac{(r^{(k)})^\top M^{-1} A d^{(k-1)}}{(d^{(k-1)})^\top A d^{(k-1)}}. \quad (4.24)$$

Interestingly, the algorithm obtained in this way generates search directions which are fully A -conjugate, as shown in the following result.

Lemma 4.16 (Properties of the iterates in the CG algorithm, see [Nocedal, Wright, 2006](#), Theorem 5.3). *Suppose that $x^{(0)} \in \mathbb{R}^n$ is given and that the search directions $\{d^{(0)}, d^{(1)}, \dots, d^{(k)}\}$ and the subsequent iterates $x^{(1)}, \dots, x^{(k)}$, $k \geq 1$, are generated according to (4.19)–(4.20), (4.23)–(4.24), where $\alpha^{(k)} \neq 0$.¹²*

$$\text{span}\{r^{(0)}, r^{(1)}, \dots, r^{(k)}\} = \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\}, \quad (4.25)$$

$$\text{span}\{d^{(0)}, d^{(1)}, \dots, d^{(k)}\} = M^{-1} \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\}, \quad (4.26)$$

$$(d^{(k)})^\top A d^{(i)} = 0 \quad \text{for all } i = 0, 1, \dots, k-1, \quad (4.27)$$

$$(r^{(k)})^\top M^{-1} r^{(i)} = 0 \quad \text{for all } i = 0, 1, \dots, k-1. \quad (4.28)$$

¹¹With $\beta^{(k)} = 0$, we obtain again the steepest descent method ([Algorithm 4.6](#)).

¹² $\alpha^{(k)} = 0$ would mean that $x^{(k)}$ is the unique solution x^* . Due to the form of the Cauchy step (4.20), this is clear for $k = 0$, as the nominator is $\|r^{(k)}\|_{M^{-1}}$. (4.22) shows that this is also true for $k > 0$.

The subspace

$$\mathcal{K}^{(k+1)}(A M^{-1}; r^{(0)}) := \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\} \quad (4.29)$$

is termed the **Krylov subspace** (of order $k + 1$) of the matrix $A M^{-1}$ with initial vector $r^{(0)}$. Therefore, the CG method is a representative of the class of **Krylov subspace methods**. The properties (4.25) and (4.26) imply that the method creates, simultaneously, an expanding sequence of M^{-1} -orthogonal basis vectors of the spaces $\mathcal{K}^{(k)}(A M^{-1}; r^{(0)})$, as well as an expanding sequence of A -orthogonal basis vectors of the spaces $M^{-1}\mathcal{K}^{(k)}(A M^{-1}; r^{(0)})$.

Proof. We first prove (4.25)–(4.27), by induction. For $k = 0$, statement (4.25) holds trivially. Statement (4.26) holds since the CG method starts with $d^{(0)} = -M^{-1}r^{(0)}$. Statement (4.27) is void for $k = 0$.

Suppose now that (4.25) and (4.26) have been shown up to some $k \geq 0$. We need to show that they also hold for $k + 1$. By hypothesis,

$$\begin{aligned} r^{(k)} &\in \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\}, \\ d^{(k)} &\in M^{-1} \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\}, \\ \text{hence } A d^{(k)} &\in A M^{-1} \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\} \\ &= \text{span}\{(A M^{-1}) r^{(0)}, \dots, (A M^{-1})^{k+1} r^{(0)}\}. \end{aligned}$$

Due to the residual recursion (4.21), we therefore have

$$\begin{aligned} r^{(k+1)} &= r^{(k)} + \alpha^{(k)} A d^{(k)} \\ &\in \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\} + \text{span}\{(A M^{-1}) r^{(0)}, \dots, (A M^{-1})^{k+1} r^{(0)}\} \\ &= \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^{k+1} r^{(0)}\}. \end{aligned} \quad (*)$$

Due to the induction hypothesis for (4.25), the same statement (*) holds when $k + 1$ is replaced by a smaller index. Therefore, we have shown that

$$\text{span}\{r^{(0)}, r^{(1)}, \dots, r^{(k+1)}\} \subseteq \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^{k+1} r^{(0)}\}$$

holds. Now for the reverse inequality. By the induction hypothesis for (4.26), we find

$$A M^{-1}(A M^{-1})^k r^{(0)} \in A \text{span}\{d^{(0)}, d^{(1)}, \dots, d^{(k)}\} = \text{span}\{A d^{(0)}, A d^{(1)}, \dots, A d^{(k)}\}.$$

By the residual recursion (4.21), specifically

$$A d^{(i)} = \frac{1}{\alpha^{(i)}} (r^{(i+1)} - r^{(i)}) \in \text{span}\{r^{(i)}, r^{(i+1)}\}$$

for $i = 0, 1, \dots, k$, it follows that

$$A M^{-1}(A M^{-1})^k r^{(0)} \in \text{span}\{r^{(0)}, r^{(1)}, \dots, r^{(k+1)}\}.$$

When combined with the induction hypothesis for (4.25), i. e.,

$$\text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}\} = \text{span}\{r^{(0)}, r^{(1)}, \dots, r^{(k)}\},$$

we find the desired reverse inequality

$$\text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^{k+1} r^{(0)}\} \subseteq \text{span}\{r^{(0)}, r^{(1)}, \dots, r^{(k+1)}\}.$$

Thus the induction step for (4.25) is complete.

To see (4.26),

$$\begin{aligned} & \text{span}\{d^{(0)}, \dots, d^{(k)}, d^{(k+1)}\} \\ &= \text{span}\{d^{(0)}, \dots, d^{(k)}, M^{-1} r^{(k+1)}\} && \text{by (4.23)} \\ &= M^{-1} \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}, r^{(k+1)}\} && \text{by (4.26)} \\ &= M^{-1} \text{span}\{r^{(0)}, r^{(1)}, \dots, r^{(k)}, r^{(k+1)}\} && \text{by (4.25)} \\ &= M^{-1} \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}, \dots, (A M^{-1})^k r^{(0)}, (A M^{-1})^{k+1} r^{(0)}\} && \text{by (4.25) for } k+1. \end{aligned}$$

This concludes the induction step for (4.26).

Next we address the A -conjugacy of search directions, (4.27). By the induction hypothesis, the directions $d^{(0)}, \dots, d^{(k)}$ are pairwise A -conjugate. Consider

$$(d^{(k+1)})^\top A d^{(i)} = (-M^{-1} r^{(k+1)} + \beta^{(k+1)} d^{(k)})^\top A d^{(i)} \quad (**)$$

for $i = 0, \dots, k$. In case $i = k$, we have

$$(d^{(k+1)})^\top A d^{(k)} = 0$$

by construction of the search direction $d^{(k+1)}$, see (4.23) and (4.24). When $i \leq k-1$, we argue as follows. From (4.26), we obtain

$$\begin{aligned} M^{-1} A d^{(0)} &\in M^{-1} A M^{-1} \text{span}\{r^{(0)}\} && \subseteq \text{span}\{d^{(0)}, d^{(1)}\}, \\ M^{-1} A d^{(1)} &\in M^{-1} A M^{-1} \text{span}\{r^{(0)}, (A M^{-1}) r^{(0)}\} && \subseteq \text{span}\{d^{(0)}, d^{(1)}, d^{(2)}\}, \\ &\vdots && \vdots \\ M^{-1} A d^{(k-1)} &\in M^{-1} A M^{-1} \text{span}\{r^{(0)}, \dots, (A M^{-1})^{k-1} r^{(0)}\} && \subseteq \text{span}\{d^{(0)}, \dots, d^{(k)}\}. \end{aligned}$$

We thus find that, for any $i \leq k-1$, the term $(r^{(k+1)})^\top M^{-1} A d^{(i)}$ in (**) belongs to

$$(r^{(k+1)})^\top \text{span}\{d^{(0)}, \dots, d^{(i+1)}\} = \text{span}\{(r^{(k+1)})^\top d^{(0)}, \dots, (r^{(k+1)})^\top d^{(i+1)}\}.$$

By (4.22), however, $(r^{(k+1)})^\top d^{(j)} = 0$ for $j = 0, \dots, k$. Therefore, (**) reduces to

$$(d^{(k+1)})^\top A d^{(i)} = \beta^{(k+1)} (d^{(k)})^\top A d^{(i)}. \quad (***)$$

By the induction hypothesis, this is equal to zero, which concludes the induction step for (4.27).

Finally, we consider the M^{-1} -conjugacy of residuals, (4.28), for $k \geq 1$. We do not need an induction argument for this. We consider two cases for $(r^{(k)})^\top M^{-1} r^{(i)}$:

(1) In case $i = k - 1$, we have

$$(r^{(k)})^\top M^{-1} r^{(k-1)} = \underbrace{\left\{ \begin{aligned} &(r^{(k-1)} + \alpha^{(k-1)} A d^{(k-1)})^\top (-d^{(k-1)} + \beta^{(k-1)} d^{(k-2)}) & \text{for } k \geq 2 \\ &(r^{(k-1)} + \alpha^{(k-1)} A d^{(k-1)})^\top (-d^{(k-1)}) & \text{for } k = 1 \end{aligned} \right.}_{(\square)}$$

by the residual recursion (4.21) and the construction of search directions (4.23). Since the Cauchy step size satisfies $\alpha^{(k-1)} = -\frac{(d^{(k-1)})^\top r^{(k-1)}}{(d^{(k-1)})^\top A d^{(k-1)}}$, the term (\square) is equal to zero for all $k \geq 1$. Let us consider the remaining terms when $k \geq 2$. We obtain

$$\begin{aligned} (r^{(k-1)})^\top d^{(k-2)} &= 0 \quad \text{due to (4.22),} \\ (A d^{(k-1)})^\top (d^{(k-2)}) &= 0 \quad \text{owing to the } A\text{-conjugacy of search directions.} \end{aligned}$$

Therefore we conclude that $(r^{(k)})^\top M^{-1} r^{(k-1)} = 0$ holds for all $k \geq 1$.

(2) in case $i < k - 1$, we have

$$(r^{(k)})^\top M^{-1} r^{(i)} = \begin{cases} (r^{(k-1)} + \alpha^{(k-1)} A d^{(k-1)})^\top (-d^{(i)} + \beta^{(i)} d^{(i-1)}) & \text{for } i \geq 1 \\ (r^{(k-1)} + \alpha^{(k-1)} A d^{(k-1)})^\top (-d^{(i)}) & \text{for } i = 0 \end{cases}$$

When expanding, we obtain terms of the types (note $i < k - 1$)

$$\begin{aligned} (r^{(k-1)})^\top d^{(i)} &= 0 \quad \text{due to (4.22),} \\ (A d^{(k-1)})^\top d^{(i)} &= 0 \quad \text{owing to the } A\text{-conjugacy of search directions,} \\ (r^{(k-1)})^\top d^{(i-1)} &= 0 \quad \text{due to (4.22),} \\ (A d^{(k-1)})^\top d^{(i-1)} &= 0 \quad \text{owing to the } A\text{-conjugacy of search directions.} \end{aligned}$$

Therefore we conclude that $(r^{(k)})^\top M^{-1} r^{(i)} = 0$ holds for all $k \geq 1$ and $0 \leq i < k - 1$. \square

Using the properties of the iterates shown above, the equations (4.20) for $\alpha^{(k)}$ as well as (4.24) for $\beta^{(k)}$ in the CG method can be equivalently formulated as follows:

$$\begin{aligned} \alpha^{(k)} &= -\frac{(r^{(k)})^\top \mathbf{d}^{(k)}}{(d^{(k)})^\top A d^{(k)}} && \text{by the Cauchy step size formula (4.20)} \\ &= \frac{(r^{(k)})^\top M^{-1} r^{(k)}}{(d^{(k)})^\top A d^{(k)}} - \beta^{(k)} \frac{(r^{(k)})^\top d^{(k-1)}}{(d^{(k)})^\top A d^{(k)}} && \text{by the search direction recursion (4.23)} \\ &= \frac{(r^{(k)})^\top M^{-1} r^{(k)}}{(d^{(k)})^\top A d^{(k)}} && \text{by (4.22)} \end{aligned} \tag{4.20'}$$

and

$$\begin{aligned} \beta^{(k+1)} &= \frac{(r^{(k+1)})^\top M^{-1} A d^{(k)}}{(d^{(k)})^\top A d^{(k)}} && \text{by the orthogonalization coefficient (4.24)} \\ &= \frac{(r^{(k+1)})^\top M^{-1} (r^{(k+1)} - r^{(k)})}{(d^{(k)})^\top (r^{(k+1)} - r^{(k)})} && \text{by the residual recursion (4.21)} \\ &= \frac{(r^{(k+1)})^\top M^{-1} (r^{(k+1)} - r^{(k)})}{(-M^{-1} r^{(k)} + \beta^{(k)} d^{(k-1)})^\top (r^{(k+1)} - r^{(k)})} && \text{by the construction of search directions (4.23)} \\ &= \frac{(r^{(k+1)})^\top M^{-1} r^{(k+1)}}{(r^{(k)})^\top M^{-1} r^{(k)}} && \text{by (4.22) and (4.25).} \end{aligned} \tag{4.24'}$$

The relations (4.20') and (4.24') are also true for $k = 0$.

We have now obtained the common form of the CG method w.r.t. the M -inner product, commonly referred to as the **preconditioned conjugate gradient method**.

Algorithm 4.17 (Conjugate gradient method for (4.1) w.r.t. the M -inner product).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: right-hand side $b \in \mathbb{R}^n$

Input: s. p. d. matrix A (or matrix-vector products with A)

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Output: approximate solution of (4.1), i. e., of $Ax = b$

```

1: Set  $k := 0$ 
2: Set  $r^{(0)} := Ax^{(0)} - b$                                      // evaluate the initial residual
3: Set  $d^{(0)} := -M^{-1}r^{(0)}$                                    // evaluate the initial negative M-gradient
4: Set  $\delta^{(0)} := -(r^{(0)})^\top d^{(0)}$                            //  $\delta^{(0)} = \|\nabla_M \phi(x^{(0)})\|_M^2 = \|r^{(0)}\|_{M^{-1}}^2$ 
5: while stopping criterion not met do
6:   Set  $q^{(k)} := Ad^{(k)}$ 
7:   Set  $\theta^{(k)} := (q^{(k)})^\top d^{(k)}$ 
8:   Set  $\alpha^{(k)} := \delta^{(k)} / \theta^{(k)}$                            // evaluate the Cauchy step size
9:   Set  $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$                        // update the iterate
10:  Set  $r^{(k+1)} := r^{(k)} + \alpha^{(k)} q^{(k)}$                      // update the residual
11:  Set  $d^{(k+1)} := -M^{-1}r^{(k+1)}$                              // evaluate the negative M-gradient
12:  Set  $\delta^{(k+1)} := -(r^{(k+1)})^\top d^{(k+1)}$                  //  $\delta^{(k+1)} = \|\nabla_M \phi(x^{(k+1)})\|_M^2 = \|r^{(k+1)}\|_{M^{-1}}^2$ 
13:  Set  $\beta^{(k+1)} := \delta^{(k+1)} / \delta^{(k)}$                        // evaluate the A-orthogonalization coefficient
14:  Set  $d^{(k+1)} := d^{(k+1)} + \beta^{(k+1)} d^{(k)}$                  // make  $d^{(k+1)}$  A-orthogonal w.r.t.  $d^{(k)}$ 
15:  Set  $k := k + 1$ 
16: end while
17: return  $x^{(k)}$ 

```

Remark 4.18 (on Algorithm 4.17).

- (i) From Lemma 4.16 we know that the CG method generates pairwise A -orthogonal directions, although it only needs to orthogonalize any new direction $d^{(k+1)}$ against the most recent one, $d^{(k)}$. This phenomenon, known as **short-term recurrence**, is possible due to the symmetry of A .
- (ii) The conjugate thus keeps a memory of previously visited directions, although this memory is mainly implicit. As shown in Algorithm 4.17, we can implement the method with a constant amount of storage.
- (iii) The implementation of the CG method is very similar to the steepest descent method (Algorithm 4.6). The only (but significant!) difference lies in the fact that we A -orthogonalize the steepest descent direction against $d^{(k)}$ before we use it as the new search direction $d^{(k+1)}$. The initial search direction $d^{(0)}$ is the steepest descent direction for ϕ at $x^{(0)}$. Consequently, the iterate $x^{(1)}$ is the same for the conjugate gradient method and the steepest descent method with Cauchy step size (Algorithm 4.6).

- (iv) The name **conjugate gradient method** is a bit of a misnomer, since it is not the gradients which are A -conjugate, but rather the search directions $d^{(k)}$.
- (v) **Remark 4.7** remains valid for the conjugate gradient method as well, with minor modifications. We need to store one additional vector since $d^{(k)}$ and $d^{(k+1)}$ are needed simultaneously.
- (vi) The stopping criteria (4.14) and their consequences (4.15) continue to hold since they depend on the same computable quantity $\|r^{(k)}\|_{M^{-1}}$ as in the steepest descent method.

Our next goal is to establish a convergence result for the conjugate gradient method, and to compare it to **Theorem 4.8** for the steepest descent method with Cauchy step size. A major difference is that we will not obtain a result about the reduction of the error from iteration to iteration, but rather a result about the reduction of the error compared with its initial value.

Theorem 4.19 (Convergence of **Algorithm 4.17**, compare **Theorem 4.8**). Suppose that $A \in \mathbb{R}^{n \times n}$ and M are both s. p. d., $\alpha := \lambda_{\min}(A; M)$ and $\beta := \lambda_{\max}(A; M)$ are the extremal generalized eigenvalues of A w.r.t. M . Then for any choice of the initial guess $x^{(0)}$, the conjugate gradient method converges to the unique solution $x^* = A^{-1}b$ of (4.1). In terms of the generalized condition number $\kappa = \beta/\alpha$, we have the estimates¹³

$$\phi(x^{(k)}) - \phi(x^*) \leq 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k} (\phi(x^{(0)}) - \phi(x^*)) \quad (4.30a)$$

$$\|x^{(k)} - x^*\|_A \leq 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^k \|x^{(0)} - x^*\|_A, \quad (4.30b)$$

Moreover, the objective values $\phi(x^{(k)})$ and thus the norm of the error $\|x^{(k)} - x^*\|_A$ are monotonically decreasing.

Proof. Since the search directions, by (4.26), span $M^{-1}\mathcal{K}^{(k)}(AM^{-1}; r^{(0)})$, we have

$$x^{(k)} - x^{(0)} \in M^{-1}\mathcal{K}^{(k)}(AM^{-1}; r^{(0)}).$$

In other words, we have

$$x^{(k)} - x^{(0)} = q^{(k-1)}(M^{-1}A)M^{-1}r^{(0)}$$

for some polynomial $q^{(k-1)}$ in the matrix $M^{-1}A$ of degree at most $k-1$. Abbreviating $e^{(k)} := x^{(k)} - x^*$ and using $Ae^{(0)} = Ax^{(0)} - Ax^* = r^{(0)}$, we can manipulate this equation into

$$\begin{aligned} e^{(k)} &= e^{(0)} + q^{(k-1)}(M^{-1}A)M^{-1}r^{(0)} \\ &= e^{(0)} + q^{(k-1)}(M^{-1}A)M^{-1}Ae^{(0)} \\ &= [\text{Id} + q^{(k-1)}(M^{-1}A)M^{-1}A]e^{(0)} \\ &= p^{(k)}(M^{-1}A)e^{(0)}, \end{aligned}$$

where now $p^{(k)}$ is a polynomial of degree at most k satisfying $p^{(k)}(0) = 1$.

¹³compare (4.13c), (4.13d)

By construction, the conjugate gradient method minimizes $\|e^{(k)}\|_A$ in every iteration. We can now express this in terms of a minimization over the vector space Π_k of polynomials of degree $\leq k$:

$$\|e^{(k)}\|_A = \min \left\{ \|p(M^{-1}A) e^{(0)}\|_A \mid p \in \Pi_k, p(0) = 1 \right\}. \quad (4.31)$$

We expand the initial error $e^{(0)}$ in terms of the basis of eigenvectors of A w.r.t. M ; see (2.10), (2.11). Suppose we denote the generalized eigenpairs by $(\lambda^{(j)}, v^{(j)})$, we can write

$$e^{(0)} = \sum_{j=1}^n \gamma^{(j)} v^{(j)}$$

with some coefficients $\gamma^{(j)}$ determined by $e^{(0)}$. We can thus manipulate the objective in the minimization problem above as follows:

$$\begin{aligned} \|p(M^{-1}A) e^{(0)}\|_A &= \left\| p(M^{-1}A) \left(\sum_{j=1}^n \gamma^{(j)} v^{(j)} \right) \right\|_A \\ &= \left\| \sum_{j=1}^n \gamma^{(j)} p(M^{-1}A) v^{(j)} \right\|_A \end{aligned}$$

In view of $A v^{(j)} = \lambda^{(j)} M v^{(j)}$ and thus $M^{-1}A v^{(j)} = \lambda^{(j)} v^{(j)}$, this is

$$= \left\| \sum_{j=1}^n \gamma^{(j)} p(\lambda^{(j)}) v^{(j)} \right\|_A.$$

By pulling the maximal value of $|p(\lambda^{(j)})|$ out of the sum (**Quiz 4.6:** Can you fill in the details why this is possible?), we can estimate this quantity further:

$$\begin{aligned} &\leq \max_{j=1, \dots, n} |p(\lambda^{(j)})| \left\| \sum_{j=1}^n \gamma^{(j)} v^{(j)} \right\|_A \\ &= \max_{j=1, \dots, n} |p(\lambda^{(j)})| \|e^{(0)}\|_A. \end{aligned}$$

Combining this with (4.31), we see

$$\begin{aligned} \|e^{(k)}\|_A &\leq \min \left\{ \max_{j=1, \dots, n} |p(\lambda^{(j)})| \|e^{(0)}\|_A \mid p \in \Pi_k, p(0) = 1 \right\} \\ &= \min \left\{ \max_{j=1, \dots, n} |p(\lambda^{(j)})| \mid p \in \Pi_k, p(0) = 1 \right\} \|e^{(0)}\|_A \end{aligned}$$

and since the eigenvalues lie in the interval $[\alpha, \beta]$,

$$\|e^{(k)}\|_A \leq \min \left\{ \max_{z \in [\alpha, \beta]} |p(z)| \mid p \in \Pi_k, p(0) = 1 \right\} \|e^{(0)}\|_A. \quad (4.32)$$

We have thus estimated $\frac{\|e^{(k)}\|_A}{\|e^{(0)}\|_A}$ by the smallest maximal absolute value any polynomial $p \in \Pi_k$ with $p(0) = 1$ can attain on the interval $[\alpha, \beta]$ spanning all generalized eigenvalues of A w.r.t. M .

The question about the *optimal* polynomial in (4.32) can be answered by Chebyshev polynomials; we refer you to [Elman, Silvester, Wathen, 2014](#), Theorem 2.4 if you want to know more details. It turns out that the optimal value

$$\min \left\{ \max_{z \in [\alpha, \beta]} |p(z)| \mid p \in \Pi_k, p(0) = 1 \right\}$$

depends only on $\kappa = \beta/\alpha$ and it is given by

$$\begin{aligned} &= 2 \left[\left(\frac{\sqrt{\kappa} + 1}{\sqrt{\kappa} - 1} \right)^k + \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^k \right]^{-1} \\ &\leq 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^k. \end{aligned}$$

From there, we finally obtain

$$\|e^{(k)}\|_A \leq 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^k \|e^{(0)}\|_A,$$

which is precisely (4.32). Squaring both sides and dividing by 2, we also obtain (4.30a). \square

Corollary 4.20 (Maximal number of iterations required in [Algorithm 4.17](#), compare [Corollary 4.9](#)).
Given positive numbers ε_1 and ε_2 , it takes

$$\begin{aligned} k &\leq \left\lceil \frac{\sqrt{\kappa}}{4} \ln \left(\frac{2}{\varepsilon_1} \right) \right\rceil \text{ iterations until } 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k} \leq \varepsilon_1, \\ k &\leq \left\lceil \frac{\sqrt{\kappa}}{2} \ln \left(\frac{2}{\varepsilon_2} \right) \right\rceil \text{ iterations until } 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^k \leq \varepsilon_2. \end{aligned}$$

Proof. The proof is similar to [Corollary 4.9](#) and it uses that

$$-\ln \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right) \geq \frac{2}{\sqrt{\kappa}} > 0$$

holds for all $\kappa \geq 1$. \square

Remark 4.21 (on [Theorem 4.19](#)).

- (i) The estimates (4.30a) and (4.32) establish the R -linear convergence of the respective quantities to zero.
- (ii) Compared to the estimates (4.13c) and (4.13d) for the gradient descent method, we obtain the reduction factor $\left(\frac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1} \right)^k$ in place of $\left(\frac{\kappa-1}{\kappa+1} \right)^k$, which is generally much better.
- (iii) The superiority of the CG method compared to the gradient descent method is also reflected in the estimates for the maximal iteration numbers to achieve a certain reduction in the quantities $\phi(x^{(k)}) - \phi(x^*)$ and $\|x^{(k)} - x^*\|_A$, respectively. The bounds for the maximal iteration numbers are proportional to $\sqrt{\kappa}$ for the CG method, not proportional to κ .

(a) Iterates $(x^{(k)})$ of the method. Each color corresponds to a different initial guess $x^{(0)}$.

(b) The norm of the gradient $\sqrt{\delta^{(k)}} = \|\nabla_M \phi(x^{(k)})\|_M = \|r^{(k)}\|_{M^{-1}}$ does not necessarily converge monotonically.

(c) The objective values $\phi(x^{(k)}) - \phi(x^*)$ converge monotonically. The black line illustrates the bound (4.30a).

Figure 4.3: Illustration of the convergence behavior of Algorithm 4.17 from a number of initial guesses $x^{(0)}$. No preconditioning ($M = \text{Id}$) is used. The two eigenvalues of the matrix are $\alpha = 1$ and $\beta = 10$ so the condition number is $\kappa = 10$.

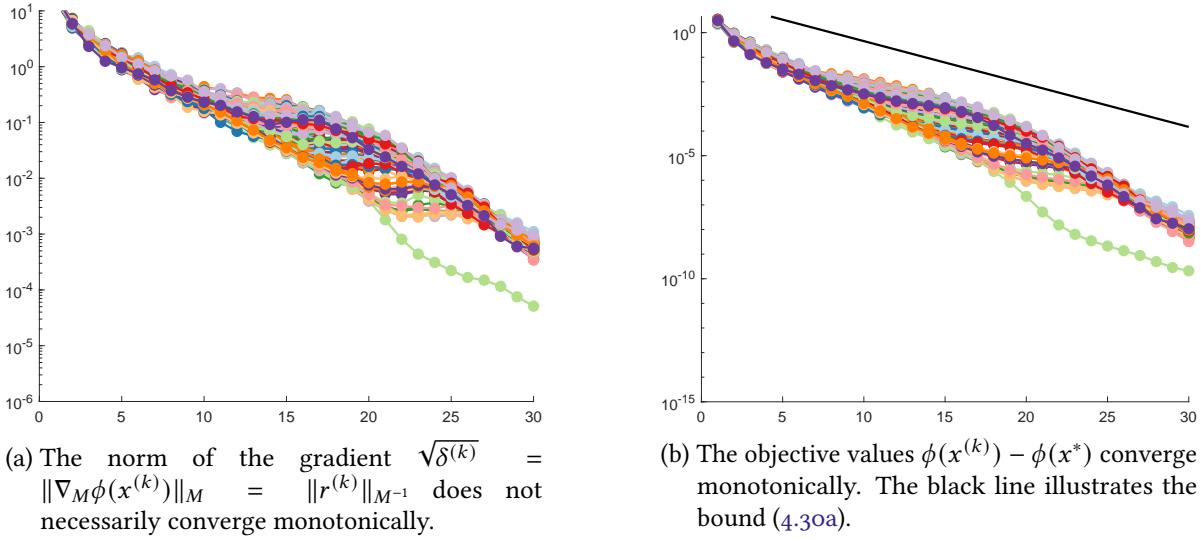

Figure 4.4: Illustration of the convergence behavior of Algorithm 4.17 from a number of initial guesses $x^{(0)}$. No preconditioning ($M = \text{Id}$) is used. Here A is a random matrix of dimension 100×100 with eigenvalues in the interval $[\alpha, \beta] = [1, 100]$ so that the condition number is $\kappa = 100$.

- (iv) As was the case for Theorem 4.8, the estimates of Theorem 4.19 are worst-case estimates since they do not depend on the initial guess $x^{(0)}$. In fact, as can be seen in Figure 4.3c and Figure 4.4b, the actual contraction factor for the objective values can be significantly smaller for some initial guesses than the estimate (4.30a) suggests.
- (v) Other informative error bounds than (4.30) and (4.32) and convergence results can be obtained by proceeding as in the proof of Theorem 4.19 and choosing other polynomials to bound the error with.

The iterates of the conjugate gradient method have a further remarkable property, which we will exploit later on:

Lemma 4.22 (Growth of the distance from the initial guess¹⁴). *Consider the iterates $x^{(k)}$ of the conjugate gradient method (Algorithm 4.17). As long as $x^{(k)} \neq x^*$ holds, the sequence $\|x^{(k)} - x^{(0)}\|_M$ is strictly increasing.*

Note: The steepest descent method does not have this property.

Proof. Statement (i) in Lemma 4.14 implies that

$$(r^{(k)})^\top (x^{(k)} - x^{(0)}) = \sum_{i=0}^{k-1} \alpha_i \underbrace{(r^{(k)})^\top d^{(i)}}_{=0} = 0 \quad \text{for all } k \geq 0. \quad (*)$$

¹⁴In the literature, we find this result often only for the case $x^{(0)} = 0$, see for instance Nocedal, Wright, 2006, Theorem 7.3.

We now show by induction that $(x^{(k)} - x^{(0)})^\top M d^{(k)} > 0$ holds for $k \geq 1$. Initially, for $k = 1$, [Statement \(i\) in Lemma 4.14](#) once again yields

$$\begin{aligned} (x^{(1)} - x^{(0)})^\top M d^{(1)} &= \alpha^{(0)} \overbrace{(d^{(0)})^\top M (-M^{-1}r^{(1)} + \beta^{(1)}d^{(0)})}^{=0} \\ &= \underbrace{\alpha^{(0)}}_{>0} \underbrace{\beta^{(1)}}_{>0} \underbrace{(d^{(0)})^\top M d^{(0)}}_{>0} \\ &> 0. \end{aligned}$$

We now proceed with the step from index k to $k + 1$:

$$\begin{aligned} (x^{(k+1)} - x^{(0)})^\top M d^{(k+1)} &= (x^{(k+1)} - x^{(0)})^\top M (-M^{-1}r^{(k+1)} + \beta^{(k+1)}d^{(k)}) \\ &= \beta^{(k+1)} (x^{(k+1)} - x^{(0)})^\top M d^{(k)} && \text{by (*)} \\ &= \beta^{(k+1)} (x^{(k)} + \alpha^{(k)}d^{(k)} - x^{(0)})^\top M d^{(k)} \\ &= \beta^{(k+1)} (x^{(k)} - x^{(0)})^\top M d^{(k)} + \alpha^{(k)}\beta^{(k+1)} (d^{(k)})^\top M d^{(k)} \\ &> 0. && (**) \end{aligned}$$

Due to the induction hypothesis as well as $\alpha^{(k)} > 0$, $\beta^{(k+1)} > 0$ and $(d^{(k)})^\top M d^{(k)} > 0$, the entire expression is positive.

The desired result now easily follows from

$$\begin{aligned} \|x^{(k+1)} - x^{(0)}\|_M^2 &= \|x^{(k)} + \alpha^{(k)}d^{(k)} - x^{(0)}\|_M^2 \\ &= \|x^{(k)} - x^{(0)}\|_M^2 + 2 \underbrace{\alpha^{(k)}}_{>0} \underbrace{(x^{(k)} - x^{(0)})^\top M d^{(k)}}_{>0} + \underbrace{(\alpha^{(k)})^2 \|d^{(k)}\|_M^2}_{>0}. \end{aligned} \quad (***)$$

□

The relations (**) and (***) allow us to compute the informative quantities

$$\omega^{(k)} := \|x^{(k)} - x^{(0)}\|_M^2 \quad (4.33a)$$

$$\xi^{(k)} := (x^{(k)} - x^{(0)})^\top M d^{(k)} \quad (4.33b)$$

$$\gamma^{(k)} := \|d^{(k)}\|_M^2 \quad (4.33c)$$

on the side without any noticeable effort. This can be achieved by inserting, at the appropriate positions in [Algorithm 4.17 \(Quiz 4.7: Where?\)](#), the relations

$$\omega^{(0)} := 0, \quad \omega^{(k+1)} := \omega^{(k)} + 2\alpha^{(k)}\xi^{(k)} + (\alpha^{(k)})^2\gamma^{(k)} \quad \text{see (***)} \quad (4.34a)$$

$$\xi^{(0)} := 0, \quad \xi^{(k+1)} := \beta^{(k+1)}(\xi^{(k)} + \alpha^{(k)}\gamma^{(k)}) \quad \text{see (**)} \quad (4.34b)$$

$$\gamma^{(0)} := \delta^{(0)}, \quad \gamma^{(k+1)} := \delta^{(k+1)} + (\beta^{(k+1)})^2\gamma^{(k)} \quad \text{(confirm for yourself).} \quad (4.34c)$$

The remarkable fact about this is the possibility to keep track of (4.33) without requiring access to the matrix M , or even matrix-vector products with M . Notice that we usually do not have the latter since we only need matrix-vector products with M^{-1} in [Algorithm 4.17](#).

§ 5 LINE SEARCH METHODS FOR NONLINEAR UNCONSTRAINED PROBLEMS

We consider in this section a large class of methods to solve general, nonlinear unconstrained problems

$$\text{Minimize } f(x) \quad \text{where } x \in \mathbb{R}^n. \quad (\text{UP})$$

The methods we consider are so-called **line search methods**. In every iteration, a line search method first determines a **search direction** and subsequently finds a **step size** (or **step length**) $\alpha^{(k)}$, that leads to the next iterate via

$$x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}.$$

Assumption 5.1. Throughout § 5 we are assuming that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is a C^1 function.

Most line search methods, in particular the ones we consider, require that $d^{(k)}$ is a **descent direction** for the objective f at the current iterate $x^{(k)}$, i. e., that

$$f'(x^{(k)}) d^{(k)} < 0 \quad (5.1)$$

holds, see Definition 4.4. This implies that we have descent at least for sufficiently small positive step sizes $\alpha^{(k)}$,

$$f(x^{(k+1)}) = f(x^{(k)} + \alpha^{(k)} d^{(k)}) < f(x^{(k)})$$

and it motivates the term **descent method**.

Most methods¹⁵ we are discussing in § 5 determine the search direction $d^{(k)}$ by considering a local **quadratic model** of the objective:

$$q^{(k)}(d) = f(x^{(k)}) + f'(x^{(k)}) d + \frac{1}{2} d^T H^{(k)} d. \quad (5.2)$$

This model uses the data $f(x^{(k)})$ and $f'(x^{(k)})$ at the iterate $x^{(k)}$ and it agrees with f regarding that data at $d = 0$:

$$\begin{aligned} q^{(k)}(0) &= f(x^{(k)}) \\ \text{and } (q^{(k)})'(0) &= f'(x^{(k)}) \end{aligned}$$

The matrix $H^{(k)}$ is the Hessian of the model, briefly: the **model Hessian**. In case $H^{(k)} = f''(x^{(k)})$, the model $q^{(k)}$ is the second-order Taylor polynomial of f at $x^{(k)}$. However, in general, the model Hessian is chosen to be any symmetric and possibly positive definite matrix. In fact, different line search methods differ w.r.t. their choice of the model Hessians $H^{(k)}$, and thus with respect to the search directions they use.

The search direction $d^{(k)}$ is obtained by minimizing (possibly only to a certain accuracy) the quadratic polynomial $q^{(k)}$:

$$\text{Minimize } q^{(k)}(d), \quad d \in \mathbb{R}^n. \quad (5.3)$$

As we know from Lemma 4.1, the following cases can occur:

¹⁵with the exception of nonlinear conjugate gradient methods

- (i) When $H^{(k)}$ is s. p. d., then the unique solution of (5.3) is given by the unique solution of the linear system

$$H^{(k)} d^{(k)} = -\nabla f(x^{(k)}). \quad (5.4)$$

- (ii) When $H^{(k)}$ is symmetric and only positive semidefinite, then (5.3) is either unbounded, or else has infinitely many minimizers. In any case, the minimizers of (5.3) are precisely the solutions of the linear system (5.4).¹⁶
- (iii) When $H^{(k)}$ is symmetric but not positive semidefinite (i. e., at least one eigenvalue of $H^{(k)}$ is negative), then (5.3) is an unbounded problem. However, the linear system (5.4) may still be uniquely solvable, or solvable with multiple solutions, or not solvable. The solutions of the linear systems (if any) are either all saddle points¹⁷ of $q^{(k)}$, or they are all global maximizers. **(Quiz 5.1:** Is this statement clear?)

To solve (5.3) and (5.4), respectively, we can employ the conjugate gradient (CG) method from § 4.6. However, it would be useful to enhance it so that it checks and reacts to the potential occurrence of non-positive eigenvalues in the model Hessian $H^{(k)}$. We will see more details on that later.

§ 5.1 A GENERIC DESCENT METHOD

We begin by considering the following model algorithm of a generic line-search descent method:

Algorithm 5.2 (Generic line-search descent method).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Output: approximately stationary point of (UP)

```

1: Set  $k := 0$ 
2: while stopping criterion not met do
3:   Determine a search direction  $d^{(k)}$  such that  $f'(x^{(k)}) d^{(k)} < 0$            // descent direction
4:   Choose a step size  $\alpha^{(k)} > 0$  such that  $f(x^{(k)} + \alpha^{(k)} d^{(k)}) < f(x^{(k)})$  // obtain descent
5:   Set  $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$                                            // take the step
6:   Set  $k := k + 1$ 
7: end while
8: return  $x^{(k)}$ 
```

In order to analyze the convergence properties of this generic algorithm and to determine further requirements for the descent directions and step sizes, we ignore the stopping criterion for now, so that Algorithm 5.2 produces infinite sequences of iterates $x^{(k)}$, search directions $d^{(k)}$ and step sizes $\alpha^{(k)}$. In practice, of course, we will use a stopping criterion to be discussed later.

¹⁶The solution set of the linear system (5.4) is either the empty set or an affine subspace of \mathbb{R}^n whose dimension agrees with the dimension of $\ker H^{(k)}$.

¹⁷A stationary point x of f is called a **saddle point** of f if the Hessian $f''(x)$ is indefinite, i. e., has at least one positive and at least one negative eigenvalue.

We will see that, in general, we cannot expect the iterates $x^{(k)}$ to converge overall, but there may be convergent subsequences with different limit points (although this rarely occurs in practice). We recall that the limit points of convergent subsequences $(x^{(k_{\ell})})$ are precisely the **accumulation points** of $(x^{(k)})$.

We would like the accumulation points of the sequence of iterates $\{x^{(k)}\}$ to be “special” points. Therefore, it would be desirable to have the following property:

$$\text{When } x^* \text{ is an accumulation of } (x^{(k)}), \text{ then } f'(x^*) = 0, \text{ i. e., } x^* \text{ is stationary.} \quad (5.5)$$

The relatively weak property (5.5) is often referred to as the **global convergence** of an algorithm. In particular, global convergence does not mean that one obtains a global minimizer. By contrast, it means that one obtains a convergence result (5.5) that is valid for arbitrary initial guesses $x^{(0)}$. Notice that (5.5) does not assert that an accumulation point even exists.¹⁸ It turns out that, in general, we cannot expect more. Under additional assumptions on f , one may be able to show stronger results, for instance

$$\|\nabla f(x^{(k)})\| \text{ has an accumulation point at } 0. \quad (5.6a)$$

$$\text{The entire sequence } \|\nabla f(x^{(k)})\| \text{ converges to } 0. \quad (5.6b)$$

$$\text{Accumulation points of } (x^{(k)}) \text{ are stationary.} \quad (5.6c)$$

$$\text{The entire sequence } (x^{(k)}) \text{ converges to a stationary point.} \quad (5.6d)$$

$$\text{The entire sequence } (x^{(k)}) \text{ converges to a local minimizer.} \quad (5.6e)$$

We will now investigate the minimal requirements on the search directions $d^{(k)}$ and step sizes $\alpha^{(k)}$ in Algorithm 5.2 that ensure global convergence in the sense of (5.5). To this end, two properties are essential:

- (1) The search directions $d^{(k)}$ are “good descent directions”.
- (2) The step sizes $\alpha^{(k)}$ are chosen so that the achievable descent along the search direction $d^{(k)}$ is “sufficiently exploited”.

We use the user-defined M -inner product in the space of optimization variables and search directions \mathbb{R}^n . Since all norms in \mathbb{R}^n are equivalent, all concepts and properties of algorithms in the remainder of § 5 are *qualitatively independent* of the choice of M . However, the choice of M is still important through its impact on the convergence properties and stopping criteria.

REQUIREMENTS ON THE DESCENT DIRECTIONS

Definition 5.3 (Admissible search directions). *Suppose that $x^{(k)}$ and $d^{(k)}$ the sequences of iterates and search (descent) directions generated by an algorithm of type Algorithm 5.2. The sequence $d^{(k)}$ of search*

¹⁸Indeed, an example such as $f(x) = x$ for $x \in \mathbb{R}$ shows that any algorithm with the global convergence property (5.5) couldn't produce an accumulation point, since f has no stationary point.

directions is termed **admissible** in case

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \rightarrow 0 \quad \Rightarrow \quad f'(x^{(k)}) \rightarrow 0. \quad (5.7)$$

Note: The admissibility is a property that the sequence of search directions generated by a particular algorithm, applied to a particular problem (objective), started from a particular initial guess may or may not possess. One is, of course, interested in designing algorithms which generate admissible search directions for arbitrary objectives f and initial guesses $x^{(0)}$.

The expression $\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M}$ is the directional derivative of f at $x^{(k)}$ in the direction $d^{(k)}$ normalized. Therefore, we can interpret the condition (5.7) as follows: when the directional derivatives in the normalized search directions converge to zero, then it is due to the derivatives converging to zero and not due to the search directions becoming inefficient (which would be the case if they become essentially M -orthogonal to the steepest descent direction $-\nabla_M f$). This reflects our first goal (item (1) above) that the search directions are “good descent directions”. (**Quiz 5.2:** Which search directions are admissible for functions $f: \mathbb{R} \rightarrow \mathbb{R}$?)

Condition (5.7) is purely qualitative. By contrast, the **angle condition**

$$\cos \angle \left(\underbrace{-\nabla_M f(x^{(k)})}_{\text{steepest descent direction}}, \underbrace{\widehat{d^{(k)}}}_{\text{chosen search direction}} \right) = \frac{(-\nabla_M f(x^{(k)}), d^{(k)})_M}{\|\nabla_M f(x^{(k)})\|_M \|d^{(k)}\|_M} = \frac{-f'(x^{(k)}) d^{(k)}}{\|f'(x^{(k)})\|_{M^{-1}} \|d^{(k)}\|_M} \geq \eta \quad (5.8)$$

with some $\eta \in (0, 1)$ is a stronger, quantitative condition, which is moreover easy to verify. It means that the angles (as measured in the M -inner product) between the chosen search directions $d^{(k)}$ and the directions of steepest descent $-\nabla_M f(x^{(k)})$ are uniformly bounded away from 90° .

Lemma 5.4 (Angle condition implies admissibility). *Suppose that $x^{(k)}$ and $d^{(k)}$ are the sequences of iterates and search (descent) directions generated by an algorithm of type Algorithm 5.2. If the angle condition (5.8) holds with some $\eta \in (0, 1)$, then the sequence $d^{(k)}$ of search directions is admissible.*

Proof. We have

$$f'(x^{(k)}) d^{(k)} = (\nabla f(x^{(k)}), d^{(k)}) = (\nabla_M f(x^{(k)}), d^{(k)})_M.$$

The angle condition (5.8) implies

$$-\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \geq \eta \|\nabla_M f(x^{(k)})\|_M = \eta \|f'(x^{(k)})^\top\|_{M^{-1}} \geq 0.$$

When the left-hand term goes to zero, then $f'(x^{(k)})$ must go to zero as well. □

As we already mentioned, almost all of the algorithms we will discuss in detail determine their search directions from the solutions of linear systems

$$H^{(k)} d^{(k)} = -\nabla f(x^{(k)}) \quad (5.4)$$

with a **symmetric and possibly positive definite** matrix $H^{(k)}$, the model Hessian. In the **s. p. d. case**, in view of

$$f'(x^{(k)}) d^{(k)} = -f'(x^{(k)}) [(H^{(k)})^{-1} \nabla f(x^{(k)})] = -\nabla f(x^{(k)})^\top (H^{(k)})^{-1} \nabla f(x^{(k)}) < 0, \quad (5.9)$$

$d^{(k)}$ is a descent direction as long as $f'(x^{(k)}) \neq 0$ holds. However, when $H^{(k)}$ is not positive definite, then $d^{(k)}$ may fail to be a descent direction.

In the s. p. d. case, we can show that as long as the sequence of model Hessians remains “well behaved”, the sequence of search directions satisfies the angle condition (5.8) and thus is admissible as well.

Lemma 5.5 (Bounded condition numbers imply the angle condition¹⁹). *Suppose that $x^{(k)}$ and $d^{(k)}$ are the sequences of iterates and search (descent) directions generated by an algorithm of type Algorithm 5.2. Suppose that the search directions are obtained from (5.4), where $H^{(k)} \in \mathbb{R}^{n \times n}$ is a sequence of s. p. d. model Hessians. Suppose, moreover, that the generalized condition numbers of $H^{(k)}$ w.r.t. M satisfy*

$$\kappa(H^{(k)}; M) := \frac{\lambda_{\max}(H^{(k)}; M)}{\lambda_{\min}(H^{(k)}; M)} \leq \bar{\kappa}.$$

Then the sequence of search directions $d^{(k)}$ satisfies the angle condition (5.8) with

$$\eta = \frac{2\sqrt{\bar{\kappa}}}{\bar{\kappa} + 1} \geq \frac{1}{\sqrt{\bar{\kappa}}}.$$

Proof. We perform a couple of equivalent reformulations of the claim to obtain

$$\begin{aligned} -\nabla f(x^{(k)})^\top d^{(k)} &\geq \frac{2\sqrt{\bar{\kappa}}}{\bar{\kappa} + 1} \|\nabla_M f(x^{(k)})\|_M \|d^{(k)}\|_M \\ \Leftrightarrow (d^{(k)})^\top H^{(k)} d^{(k)} &\geq \frac{2\sqrt{\bar{\kappa}}}{\bar{\kappa} + 1} \|M^{-1} H^{(k)} d^{(k)}\|_M \|d^{(k)}\|_M && \text{since } H^{(k)} d^{(k)} = -\nabla f(x^{(k)}) \\ \Leftrightarrow ((d^{(k)})^\top H^{(k)} d^{(k)})^2 &\geq \frac{4\bar{\kappa}}{(\bar{\kappa} + 1)^2} \|M^{-1} H^{(k)} d^{(k)}\|_M^2 \|d^{(k)}\|_M^2 \\ \Leftrightarrow \frac{((d^{(k)})^\top H^{(k)} M^{-1} H^{(k)} d^{(k)}) ((d^{(k)})^\top M d^{(k)})}{((d^{(k)})^\top H^{(k)} d^{(k)})^2} &\leq \frac{(\bar{\kappa} + 1)^2}{4\bar{\kappa}}. \end{aligned}$$

The statement in the previous line, however, is true due to the generalized Kantorovich inequality (Corollary 2.2). \square

We summarize our findings on search directions:

- the model Hessians $H^{(k)}$ have bounded condition numbers
- \Rightarrow the angle condition (5.8) holds
- \Rightarrow the search directions are admissible (5.7).

¹⁹In the literature, one often finds this result only in the case $M = \text{Id}$, and with the non-optimal bound $\eta = \frac{1}{\bar{\kappa}}$; see for instance Ulbrich, Ulbrich, 2012, p.32 or Nocedal, Wright, 2006, eq.(3.19).

REQUIREMENTS ON THE STEP SIZES

We now address the step sizes $\alpha^{(k)}$. The following example shows that the mere requirement

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) < f(x^{(k)})$$

is not sufficient to obtain a reasonable convergence behavior.

Example 5.6 (Too small step sizes²⁰). Consider the objective $f: \mathbb{R} \rightarrow \mathbb{R}$, $f(x) = x^2$, initial guess $x^{(0)} = 1$, search directions $d^{(k)} = -1$ and the Euclidean inner product $M = 1$. With step sizes $\alpha^{(k)} = \left(\frac{1}{2}\right)^{k+2}$, we obtain the sequences of iterates according to

$$x^{(k+1)} = x^{(k)} + \alpha^{(k)} (-1) = x^{(0)} - \sum_{i=0}^k \left(\frac{1}{2}\right)^{i+2} = \frac{1}{2} + \left(\frac{1}{2}\right)^{k+2}.$$

This implies $x^{(k+1)} < x^{(k)}$ and $f(x^{(k+1)}) < f(x^{(k)})$. However, $x^{(k)} \rightarrow x^* = 1/2$, which is not a stationary point of f .

The step sizes in the previous example are too small and thus they violate our second goal (item (2) above) since they do not exploit the achievable descent sufficiently well. We therefore introduce the following qualitative condition on the step sizes.

Definition 5.7 (Admissible step sizes). Suppose that $x^{(k)}$ and $d^{(k)}$ are the sequences of iterates and search (descent) directions generated by an algorithm of type [Algorithm 5.2](#). The sequence $\alpha^{(k)}$ of step sizes is termed **admissible** in case

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) \leq f(x^{(k)}) \quad \text{for all } k \in \mathbb{N}_0, \quad (5.10a)$$

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) - f(x^{(k)}) \rightarrow 0 \quad \Rightarrow \quad \frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \rightarrow 0. \quad (5.10b)$$

We can interpret (5.10b) as follows: when the progress in the objective values converges to zero, then it is due to the normalized directional derivatives converging to zero and not due to the step sizes becoming too small. In other words, admissible step sizes do make sufficient use of the descent available in the direction $d^{(k)}$.

Condition (5.10) is purely qualitative. By contrast, the condition that the step sizes be **efficient**, i. e., there exists $\theta > 0$ such that

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) \leq f(x^{(k)}) - \theta \left(\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \right)^2 \quad (5.11)$$

for all $k \in \mathbb{N}_0$ is a stronger, quantitative condition, which is moreover easy to verify.

²⁰from [Alt, 2002](#), Beispiel 4.4.1

Lemma 5.8 (Efficiency implies admissibility). *Suppose that $x^{(k)}$ and $d^{(k)}$ are the sequences of iterates and search (descent) directions generated by an algorithm of type [Algorithm 5.2](#). If the sequence of step sizes $\alpha^{(k)}$ is efficient, then it is also admissible.*

Proof. Suppose that $\alpha^{(k)}$ is efficient, i. e.,

$$0 \leq \theta \left(\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \right)^2 \leq f(x^{(k)}) - f(x^{(k)} + \alpha^{(k)} d^{(k)})$$

Therefore (5.10a) is clear. To show (5.10b), suppose

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) - f(x^{(k)}) \rightarrow 0.$$

Since θ is strictly positive, this implies

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \rightarrow 0,$$

which confirms (5.10b). □

Using the assumptions of admissible search directions and admissible step sizes, we will obtain a theorem (see [Theorem 5.9](#) below) on the global convergence of [Algorithm 5.2](#). However, in view of the expected convergence result (5.5), we will have to work with accumulation points (limits of subsequences) of the iterates. This means that we should refine the notion of admissible search directions (5.7), the notions of admissible step sizes (5.10) as well as efficient step sizes (5.11) to subsequences. We denote such subsequences here with $(x^{(k)})_{k \in K}$, where $K \subseteq \mathbb{N}_0$ is an infinite subset of the index set \mathbb{N}_0 . (**Quiz 5.3:** How does this notation relate to the notation for subsequences $(x^{(k^{(\ell)})})$ introduced in § 2.7?)

In detail, the refined conditions on subsequences read as follows:

admissible search directions:

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \xrightarrow{k \in K} 0 \quad \Rightarrow \quad f'(x^{(k)}) \xrightarrow{k \in K} 0, \quad (5.7')$$

angle condition:

$$\frac{-f'(x^{(k)}) d^{(k)}}{\|\nabla_M f(x^{(k)})\|_M \|d^{(k)}\|_M} \geq \eta \quad \text{for all } k \in K \quad (5.8')$$

admissible step sizes:

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) \leq f(x^{(k)}) \quad \text{for all } k \in \mathbb{N}_0, \quad (5.10a')$$

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) - f(x^{(k)}) \xrightarrow{k \in \mathbb{N}_0} 0 \quad \Rightarrow \quad \frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \xrightarrow{k \in K} 0, \quad (5.10b')$$

efficient step sizes:

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) \leq f(x^{(k)}) - \theta \left(\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \right)^2 \quad \text{for all } k \in K. \quad (5.11')$$

The statements of [Lemma 5.4](#) and [Lemma 5.5](#) continue to hold when restricted to subsequences. For the analog of [Lemma 5.8](#), we have to make (5.10a') an assumption rather than a conclusion.

We now show a global convergence theorem for the model [Algorithm 5.2](#).

Theorem 5.9 (Global convergence of model [Algorithm 5.2](#)). *Suppose that [Algorithm 5.2](#) generates an infinite sequence of iterates $x^{(k)}$, search directions $d^{(k)} \neq 0$ and step sizes $\alpha^{(k)}$. Suppose that x^* is an accumulation point of $x^{(k)}$ and that $(x^{(k)})_{k \in K}$ is a subsequence converging to x^* . Finally, suppose that the subsequences $(d^{(k)})_{k \in K}$ and $(\alpha^{(k)})_{k \in K}$ of search directions and step sizes are both admissible. Then $f'(x^*) = 0$.*

Note: In other words, when a generic descent algorithm ([Algorithm 5.2](#)) produces admissible search directions and admissible step sizes, then any accumulation point of the iterates is stationary.

Quiz 5.4: What goes wrong in [Example 5.6](#)?

Proof. Due to the continuity of f , we have $f(x^{(k)}) \xrightarrow{k \in K} f(x^*)$. Moreover, by admissibility of the step sizes (5.10a'), the entire sequence $f(x^{(k)})$ is monotone decreasing. Therefore, the entire sequence in fact converges: $f(x^{(k)}) \rightarrow f(x^*)$. Consequently, we also have

$$f(x^{(k+1)}) - f(x^{(k)}) = f(x^{(k)} + \alpha^{(k)} d^{(k)}) - f(x^{(k)}) \rightarrow 0.$$

The admissibility of step sizes along the subsequence, (5.10b'), implies

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|} \xrightarrow{k \in K} 0.$$

Since the search directions along the subsequence are in turn admissible, (5.7'), we can conclude

$$f'(x^{(k)}) \xrightarrow{k \in K} 0.$$

On the other hand, since f is of class C^1 , we also have

$$f'(x^{(k)}) \xrightarrow{k \in K} f'(x^*).$$

This shows $f'(x^*) = 0$. □

§ 5.2 STEP SIZE STRATEGIES

In this section we will see how efficient step sizes (5.11) or at least admissible step sizes (5.10) can be found in general.

ARMIJO BACKTRACKING LINE SEARCH

The Armijo backtracking line search is the simplest step size strategy and it is sufficient in many situations. Suppose that $d^{(k)}$ is a descent direction for f at $x^{(k)}$. In order to obtain sufficient decrease, the **Armijo condition** requires that the step size α satisfy

$$f(x^{(k)} + \alpha d^{(k)}) \leq f(x^{(k)}) + \sigma \alpha f'(x^{(k)}) d^{(k)} \quad (5.12)$$

holds. Here $\sigma \in (0, 1)$ is the given **Armijo parameter**. Using the auxiliary function (**line search function**)

$$\varphi(\alpha) := f(x^{(k)} + \alpha d^{(k)})$$

to simplify notation, we can write the Armijo condition (5.12) equivalently in the form

$$\varphi(\alpha) \leq \varphi(0) + \sigma \alpha \varphi'(0). \quad (5.12)$$

Step sizes $\alpha \geq 0$ which satisfy (5.12) are termed **Armijo step sizes**. Condition (5.12) requires that the step size α realizes at least the σ -fraction of the first-order descent suggested by the tangent of φ at $\alpha = 0$.

Notice that due to the chain rule, φ inherits the C^1 property of f , and we have

$$\varphi'(\alpha) = f'(x^{(k)} + \alpha d^{(k)}) d^{(k)} \quad (5.13a)$$

$$\text{and, in particular, } \varphi'(0) = f'(x^{(k)}) d^{(k)}. \quad (5.13b)$$

Figure 5.1: Illustration of step sizes $\alpha \geq 0$ satisfying the Armijo condition (5.12) (blue). As an example, the Armijo parameter is chosen as $\sigma = 0.07$.

We will now answer the question whether Armijo step sizes exist, and how to find them.

Lemma 5.10 (Existence of Armijo step sizes). *Suppose that d is a descent direction for f at x , and that the Armijo parameter satisfies $\sigma \in (0, 1)$. Then there exists $\bar{\alpha} > 0$ such that (5.12) holds for all $\alpha \in [0, \bar{\alpha}]$.*

Proof. φ' is continuous at 0, which implies that there exists $\bar{\alpha} > 0$ such that

$$\varphi'(\alpha) < \sigma \varphi'(0) \quad \text{holds for all } \alpha \in [0, \bar{\alpha}].$$

From [Taylor's theorem 2.4](#) we obtain that there exists $\xi \in [0, \alpha]$ such that

$$\begin{aligned} \varphi(\alpha) &= \varphi(0) + \alpha \varphi'(\xi) \\ &\leq \varphi(0) + \sigma \alpha \varphi'(0). \end{aligned}$$

Therefore, the Armijo condition (5.12) holds for all $\alpha \in [0, \bar{\alpha}]$. □

We have seen that the Armijo condition is always satisfied in an interval starting at $\alpha = 0$. However, we need to select a step size which is not too small, as demonstrated by [Example 5.6](#). This can be achieved by a **backtracking strategy**: run through a sequence of trial step sizes **from large to small** until the Armijo condition (5.12) is satisfied for the first time.

Algorithm 5.11 (Armijo backtracking line search).

Input: initial trial step size α

Input: routine to evaluate φ

Input: pre-computed function values $\varphi(0)$ and $\varphi'(0)$

Input: Armijo parameter $\sigma \in (0, 1)$

Input: backtracking parameter $\beta \in (0, 1)$

Output: step size α satisfying the Armijo condition (5.12)

```

1: Set  $\ell := 0$ 
2: while Armijo condition (5.12) does not hold for  $\alpha$  do
3:   Set  $\alpha := \beta \alpha$  // new trial step size
4:   Set  $\ell := \ell + 1$ 
5: end while
6: return  $\alpha$ 

```

Remark 5.12 (on [Algorithm 5.11](#)).

- (i) In [Algorithm 5.11](#), we did not number the trial step sizes $\alpha^{(0)}, \alpha^{(1)}, \dots$ by an index in order to avoid confusion with the step size $\alpha^{(k)}$ which eventually gets used in the k -th iteration of the outer algorithm ([Algorithm 5.2](#)).
- (ii) Every trial step size that fails to satisfy the Armijo condition “costs” one additional evaluation of φ , i. e., one additional evaluation of f .
- (iii) The Armijo parameter is often chosen to be small, e. g., $\sigma = 10^{-2}$ or even $\sigma = 10^{-4}$. A typical value for the backtracking parameter is $\beta = 1/2$.
- (iv) It follows from [Lemma 5.10](#) that [Algorithm 5.11](#) terminates successfully after finitely many iterations with a step size α that satisfies $\alpha \geq \bar{\alpha} \beta$. Here $\bar{\alpha} > 0$ is the upper bound of any interval $[0, \bar{\alpha}]$ containing only Armijo step sizes.

- (v) In a practical implementation, one often adds further checks and stopping criteria to [Algorithm 5.11](#). For instance, we need to safeguard against $\varphi'(0) \geq 0$ (d is not a descent direction) and against too many unsuccessful trial steps.

Suitable values for the initial trial step size α in [Algorithm 5.11](#) depend on how the search directions $d^{(k)}$ are generated in the outer method. We will see more on that when we discuss concrete instances of [Algorithm 5.2](#). Since the backtracking strategy only shortens the initial trial step size, we need to ensure that the initial trial step size is sufficiently large in order to obtain admissible step sizes that exploit the achievable descent sufficiently well. This is what the following result is about.

Lemma 5.13 (Armijo backtracking line search produces admissible step sizes). *Suppose that [Algorithm 5.2](#) generates an infinite sequence of iterates $x^{(k)}$ and search (descent) directions $d^{(k)} \neq 0$. Suppose moreover that the step sizes $\alpha^{(k)}$ are obtained by the Armijo backtracking line search ([Algorithm 5.11](#)) with initial trial step size $\alpha^{(k,0)}$. Assume that $K \subseteq \mathbb{N}_0$ is an infinite index set such that the subsequence $(x^{(k)})_{k \in K}$ is bounded. Finally, suppose that $\psi: [0, \infty \rightarrow [0, \infty)$ is any monotone increasing function and that the initial trial step sizes satisfy*

$$\alpha^{(k,0)} \|d^{(k)}\|_M \geq \psi\left(\frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M}\right) \quad \text{for all } k \in K. \quad (5.14)$$

Then the step sizes $(\alpha^{(k)})_{k \in K}$ are admissible.

Proof. We need to show (5.10a') and (5.10b'). The first condition is a direct consequence of the Armijo condition holding at $\alpha^{(k)} > 0$

$$f(x^{(k)} + \alpha^{(k)} d^{(k)}) \leq f(x^{(k)}) + \underbrace{\sigma \alpha^{(k)} f'(x^{(k)}) d^{(k)}}_{<0},$$

the fact that $d^{(k)}$ is a descent direction and that σ is positive. It remains to verify (5.10b').

By assumption, the sequence $(x^{(k)})_{k \in K}$ is bounded. Therefore, it has a convergent subsequence with index set K' . By continuity of f , $(f(x^{(k)}))_{k \in K'}$ converges. Due to the Armijo condition (5.12), the sequence $f(x^{(k)})$ is monotone decreasing, so that in fact the entire sequence $f(x^{(k)})$ converges. From there and the Armijo condition (5.12) we conclude

$$f(x^{(k+1)}) - f(x^{(k)}) = f(x^{(k)} + \alpha^{(k)} d^{(k)}) - f(x^{(k)}) \leq \sigma \alpha^{(k)} f'(x^{(k)}) d^{(k)} < 0.$$

The left-hand side converges to 0, therefore we must have

$$\alpha^{(k)} f'(x^{(k)}) d^{(k)} \rightarrow 0. \quad (*)$$

In order to verify (5.10b'), we need to show

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \xrightarrow{k \in K} 0.$$

In the remainder of the proof, we distinguish indices $k \in K$ according to the following cases:

When $\alpha^{(k)} \|d^{(k)}\|_M$ is “large”, then $\frac{\alpha^{(k)} f'(x^{(k)}) d^{(k)}}{\alpha^{(k)} \|d^{(k)}\|_M}$ is small.

When $\alpha^{(k)} \|d^{(k)}\|_M$ is “small”, then $\begin{cases} \text{we use the assumption (5.14)} & \text{in case } \alpha^{(k)} = \alpha^{(k,0)}. \\ \text{we use the Armijo condition (5.12)} & \text{in case } \alpha^{(k)} < \alpha^{(k,0)}. \end{cases}$

By assumption, the sequence $(x^{(k)})_{k \in K}$ is bounded, hence the continuous function f' is uniformly continuous “near the $(x^{(k)})_{k \in K}$ ”. More precisely, suppose that $R > 0$ is any fixed number, then f' is uniformly continuous on the compact set

$$A_R := \text{cl} \bigcup_{k \in K} B_R^M(x^{(k)}).$$

(Quiz 5.5: Why is this set compact?) Now suppose that $\varepsilon > 0$ is given. Then there exists $\bar{\delta} > 0$ such that

$$\|f'(y) - f'(z)\|_{M^{-1}} \leq (1 - \sigma) \varepsilon$$

holds for all $y, z \in A_R$ such that $\|y - z\|_M \leq \bar{\delta}$. Possibly by making $\bar{\delta}$ smaller, we can assume $\bar{\delta} \leq R$. Thus, in particular, we obtain

$$\left\| \underbrace{f'(x^{(k)} + e)}_{\in A_R} - \underbrace{f'(x^{(k)})}_{\in A_R} \right\|_{M^{-1}} \leq (1 - \sigma) \varepsilon \quad \text{for all } k \in K, \quad \|e\|_M \leq \bar{\delta}. \quad (**)$$

We now set

$$\delta := \min\{\bar{\delta} \beta, \psi(\varepsilon)\} \in (0, \bar{\delta}).$$

Due to the convergence in (*), there exists an index $k_0 \in \mathbb{N}_0$ such that

$$\alpha^{(k)} |f'(x^{(k)}) d^{(k)}| \leq \varepsilon \delta \quad \text{holds for all } k \geq k_0. \quad (***)$$

From now on, let $k \in K, k \geq k_0$, be arbitrary. We are going to show that

$$0 \leq \frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \leq \varepsilon$$

holds, which proves (5.10b'). We distinguish the following cases, as anticipated above:

Case 1: $\alpha^{(k)} \|d^{(k)}\|_M \geq \delta$

In this case we immediately conclude

$$\begin{aligned} 0 &\leq \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} && \text{since } d^{(k)} \text{ is a descent direction} \\ &= \frac{-\alpha^{(k)} f'(x^{(k)}) d^{(k)}}{\alpha^{(k)} \|d^{(k)}\|_M} \\ &\leq \frac{\varepsilon \delta}{\delta} && \text{by (***) and the assumption in case 1} \\ &= \varepsilon. \end{aligned}$$

Case 2: $\alpha^{(k)} \|d^{(k)}\|_M < \delta$ and $\alpha^{(k)} = \alpha^{(k,0)}$

We obtain

$$\begin{aligned} \psi\left(\frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M}\right) &\leq \alpha_{k,0} \|d^{(k)}\|_M \quad \text{by assumption (5.14)} \\ &< \delta \quad \text{by the assumption in case 2} \\ &\leq \psi(\varepsilon) \quad \text{by the choice of } \delta. \end{aligned}$$

Since ψ is monotone increasing, we conclude

$$0 \leq \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \leq \varepsilon.$$

Case 3: $\alpha^{(k)} \|d^{(k)}\|_M < \delta$ and $\alpha^{(k)} < \alpha^{(k,0)}$

The assumption $\alpha^{(k)} < \alpha^{(k,0)}$ means that the initial trial step size (and possibly some of the subsequent trial step sizes) did not satisfy the Armijo condition. Since $\alpha^{(k)}$ was the first trial step size to satisfy the Armijo condition (5.12), the previous trial step size, $\beta^{-1}\alpha^{(k)}$, violated it:

$$\sigma \beta^{-1}\alpha^{(k)} f'(x^{(k)}) d^{(k)} < f(x^{(k)} + \beta^{-1}\alpha^{(k)} d^{(k)}) - f(x^{(k)}).$$

By [Taylor's theorem 2.4](#), there exists $\xi^{(k)} \in (0, 1)$ such that

$$\sigma \beta^{-1}\alpha^{(k)} f'(x^{(k)}) d^{(k)} < \beta^{-1}\alpha^{(k)} f'(x^{(k)} + \beta^{-1}\alpha^{(k)} \xi^{(k)} d^{(k)}) d^{(k)}$$

and thus

$$\begin{aligned} &\sigma f'(x^{(k)}) d^{(k)} \\ &< f'(x^{(k)} + \beta^{-1}\alpha^{(k)} \xi^{(k)} d^{(k)}) d^{(k)} \\ &= f'(x^{(k)}) d^{(k)} + [f'(x^{(k)} + \beta^{-1}\alpha^{(k)} \xi^{(k)} d^{(k)}) - f'(x^{(k)})] d^{(k)} \\ &\leq f'(x^{(k)}) d^{(k)} + \underbrace{\|f'(x^{(k)} + \beta^{-1}\alpha^{(k)} \xi^{(k)} d^{(k)}) - f'(x^{(k)})\|_{M^{-1}}}_{=: e^{(k)}} \|d^{(k)}\|_M \quad \text{by (2.3).} \end{aligned}$$

The vector $e^{(k)}$ satisfies

$$\begin{aligned} \|e^{(k)}\|_M &= \beta^{-1}\alpha^{(k)} \xi^{(k)} \|d^{(k)}\|_M \\ &< \beta^{-1}\delta \quad \text{by the assumption in case 3 and since } \xi^{(k)} \in (0, 1) \\ &\leq \bar{\delta} \quad \text{by the choice of } \delta. \end{aligned}$$

We may thus apply estimate (**) to the inequality above to obtain

$$\sigma f'(x^{(k)}) d^{(k)} \leq f'(x^{(k)}) d^{(k)} + (1 - \sigma) \varepsilon \|d^{(k)}\|_M.$$

Sorting terms and dividing by $\|d^{(k)}\|_M$ finally yields

$$0 \leq \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \leq \varepsilon.$$

□

Remark 5.14 (Armijo backtracking line search produces efficient step sizes). *When we choose $\psi(z) = c z$ with some $c > 0$, i. e., when we use initial trial step sizes satisfying*

$$\alpha_{k,0} \|d^{(k)}\|_M \geq c \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M}, \quad (5.15)$$

and if f' is Lipschitz continuous on the sublevel set $\mathcal{M}_f(x^{(0)}) := \{x \in \mathbb{R}^n \mid f(x) \leq f(x^{(0)})\}$, then one can show that [Algorithm 5.11](#) produces not only admissible, but efficient step sizes.

To conclude the presentation of Armijo backtracking strategies, we consider a modification of [Algorithm 5.11](#) which often produces trial step sizes more effectively than simple backtracking $\alpha \rightsquigarrow \beta \alpha$ in case the Armijo condition fails on the initial trial step size.

The modification is based on the fact that we have available the data of the line search function φ

$$\varphi(0), \quad \varphi'(0) < 0 \quad \text{and} \quad \varphi(\alpha)$$

for the current trial step size α . Using this data, we can fit a quadratic polynomial

$$p(\alpha) = a + b \alpha + c \alpha^2.$$

The conditions²¹ $p(0) = \varphi(0)$, $p'(0) = \varphi'(0)$ and $p(\alpha) = \varphi(\alpha)$ uniquely define the coefficients

$$a = \varphi(0), \quad b = \varphi'(0), \quad c = \frac{1}{\alpha^2} (\varphi(\alpha) - \varphi(0) - \varphi'(0) \alpha). \quad (5.16)$$

Naturally, this quadratic model of φ will be used only when the Armijo condition (5.12) failed at the trial step size α , i. e., in case

$$\varphi(\alpha) - \varphi(0) - \varphi'(0) \alpha > \varphi(\alpha) - \varphi(0) - \sigma \varphi'(0) \alpha > 0$$

holds, which implies $c > 0$. This in turn means that the unique global minimizer $\alpha^* = -\frac{b}{2c}$ of p satisfies

$$\alpha^* = \frac{-\varphi'(0) \alpha^2}{2 (\varphi(\alpha) - \varphi(0) - \varphi'(0) \alpha)} > 0.$$

We then choose α^* as the next trial step size α^+ , but in order to avoid drastic changes or even an increase from α to α^+ , we clip α^* to the interval $[\underline{\beta} \alpha, \bar{\beta} \alpha]$ according to

$$\alpha^+ := \min\{\max\{\alpha^*, \underline{\beta} \alpha\}, \bar{\beta} \alpha\} = \begin{cases} \underline{\beta} \alpha, & \text{if } \alpha^* < \underline{\beta} \alpha, \\ \alpha^*, & \text{if } \underline{\beta} \alpha \leq \alpha^* \leq \bar{\beta} \alpha, \\ \bar{\beta} \alpha, & \text{if } \alpha^* > \bar{\beta} \alpha, \end{cases}$$

where $0 < \underline{\beta} < \bar{\beta} < 1$ are the clipping parameters.²² This modified Armijo backtracking line search maintains the essential properties of the simple Armijo backtracking line search. In particular, the admissibility (and potentially efficiency) of the accepted step sizes (see [Lemma 5.13](#) and [Remark 5.14](#)) continue to hold.

For completeness, we present the modified Armijo backtracking line search procedure in [Algorithm 5.15](#).

²¹Fitting a polynomial using function values and derivatives is known as **Hermite interpolation**. Using function values only is known as **Lagrange interpolation**.

²²Using $\underline{\beta} = \bar{\beta} = \beta$ we get back our previous simple backtracking strategy where $\alpha^+ = \beta \alpha$.

Algorithm 5.15 (Modified Armijo backtracking line search with interpolation).

Input: initial trial step size α

Input: routine to evaluate φ

Input: pre-computed function values $\varphi(0)$ and $\varphi'(0)$

Input: Armijo parameter $\sigma \in (0, 1)$

Input: backtracking parameters $0 < \underline{\beta} < \overline{\beta} < 1$

Output: step size α satisfying the Armijo condition (5.12)

```

1: Set  $\ell := 0$ 
2: while Armijo condition (5.12) does not hold for  $\alpha$  do
3:   Set  $\alpha^* := \frac{-\varphi'(0) \alpha^2}{2(\varphi(\alpha) - \varphi(0) - \varphi'(0) \alpha)}$  // minimizer of quadratic polynomial

WOLFE-POWELL LINE SEARCH

Recall from Lemma 5.10 that the Armijo condition

$$f(x^{(k)} + \alpha d^{(k)}) \leq f(x^{(k)}) + \sigma \alpha f'(x^{(k)}) d^{(k)} \quad \text{or} \quad \varphi(\alpha) \leq \varphi(0) + \sigma \alpha \varphi'(0) \quad (5.12)$$

always holds in some interval $[0, \bar{\alpha}]$. Therefore, we combined the Armijo condition with backtracking, where we generate trial step sizes from large to small, in order to avoid overly small step sizes.

Alternatively, we could require, in addition to (5.12), the **curvature condition**

$$f'(x^{(k)} + \alpha d^{(k)}) d^{(k)} \geq \tau f'(x^{(k)}) d^{(k)} \quad \text{or} \quad \varphi'(\alpha) \geq \tau \varphi'(0) \quad (5.17)$$

or even the **strong curvature condition**

$$|f'(x^{(k)} + \alpha d^{(k)}) d^{(k)}| \leq -\tau f'(x^{(k)}) d^{(k)} \quad \text{or} \quad |\varphi'(\alpha)| \leq -\tau \varphi'(0) \quad (5.18)$$

to hold, where $\tau \in (\sigma, 1)$ is the **curvature parameter**. The curvature condition (5.17) demands that the derivative of φ at α is not too negative, namely that it is larger (has less descent) than at $\alpha = 0$. However, it would be fine for φ to increase near α ; see Figure 5.2. This curvature condition already avoids too small step sizes α near 0.

The strong curvature condition (5.18) demands that, in addition, the derivative of φ at α is not too positive either. The condition can be interpreted as the requirement that α be an approximately stationary point of φ . **Note:** When α is a local minimizer of φ , then (5.18) holds even for $\tau = 0$.

The Armijo condition (5.12) and the curvature condition (5.17) together are referred to as the **Wolfe-Powell conditions**. The Armijo condition (5.12) and the strong curvature condition (5.18) together are referred to as the **strong Wolfe-Powell conditions**. Consequently, step sizes $\alpha \geq 0$ which satisfy the above conditions are referred to as **Wolfe-Powell step sizes** and **strong Wolfe-Powell step sizes**, respectively.

Figure 5.2: Illustration of step sizes $\alpha \geq 0$ satisfying the curvature condition (5.17) (red) and the strong curvature condition (5.18) (teal). As an example, the curvature parameter is chosen as $\tau = 0.2$.

A simple example such as $\varphi(\alpha) = -\alpha$ shows that the curvature condition may not be satisfiable without further assumptions on f . The following result gives a sufficient condition for strong Wolfe-Powell step sizes to exist.

Lemma 5.16 (Existence of (strong) Wolfe-Powell step sizes). *Suppose that d is a descent direction for f at x and that the Armijo and curvature parameters satisfy $0 < \sigma < \tau < 1$. Suppose, moreover, that f is bounded below on the ray $\{x + \alpha d \mid \alpha \geq 0\}$. Then there exists a step size $\alpha_2 > 0$ such that the strong Wolfe-Powell conditions (5.12) and (5.18) (and thus also the regular Wolfe-Powell conditions (5.12) and (5.17)) hold in a neighborhood of α_2 .*

Proof. We abbreviate as usual $\varphi(\alpha) := f(x + \alpha d)$. Since by assumption, φ is bounded below on $\mathbb{R}_{\geq 0}$, φ intersects the Armijo line

$$\alpha \mapsto \varphi(0) + \underbrace{\sigma \varphi'(0)}_{<0} \alpha,$$

which is unbounded below, in at least one positive point. Suppose that α_1 is the smallest positive point of intersection (**Quiz 5.6:** Why does α_1 exist?). Then we have

$$\varphi(\alpha_1) = \varphi(0) + \sigma \varphi'(0) \alpha_1.$$

In view of $\varphi'(0) < 0$, the Armijo condition (5.12) holds for all $\alpha \in [0, \alpha_1]$, i. e., the Armijo line lies below φ on this interval. From the [mean value theorem 2.4](#), we infer the existence of $\alpha_2 \in (0, \alpha_1)$ such that

$$\varphi'(\alpha_2) = \frac{\varphi(\alpha_1) - \varphi(0)}{\alpha_1} = \sigma \varphi'(0).$$

And thus we obtain the strong curvature condition (5.18) at α_2 :

$$|\varphi'(\alpha_2)| = -\sigma \varphi'(0) < -\tau \varphi'(0).$$

Figure 5.3: Illustration of step sizes $\alpha \geq 0$ satisfying both the Armijo condition (5.12) (blue), the curvature condition (5.17) (red) and the strong curvature condition (5.18) (teal). As an example, the Armijo parameter is chosen as $\sigma = 0.07$ and the curvature parameter is chosen as $\tau = 0.2$.

Due to the continuity of φ' , the strong curvature condition (5.18) and thus also the regular curvature condition (5.17) continue to hold for all α in a neighborhood of α_2 . \square

We now address an algorithm to find a Wolfe-Powell step size. To simplify notation, we introduce the auxiliary function

$$\psi(\alpha) := \varphi(\alpha) - \varphi(0) - \sigma \varphi'(0) \alpha,$$

which measures the signed gap between the function values of the one dimensional line search function φ and its σ -relaxed linearization at the origin, so that we can write

$$\text{the Armijo condition (5.12)} \iff \psi(\alpha) \leq 0, \quad (5.12')$$

$$\text{the curvature condition (5.17)} \iff -(\tau - \sigma) |\varphi'(0)| \leq \psi'(\alpha), \quad (5.17')$$

$$\text{the strong curvature condition (5.18)} \iff \underbrace{-(\tau - \sigma)}_{>0} |\varphi'(0)| \leq \psi'(\alpha) \leq (\tau + \sigma) |\varphi'(0)|. \quad (5.18')$$

We restrict the discussion to the regular Wolfe-Powell condition, i. e., (5.12) and (5.17). See for instance Geiger, Kanzow, 1999, Kapitel 6.3 for the strong Wolfe-Powell condition.

Lemma 5.17 (Inclusion of Wolfe-Powell step sizes, see Geiger, Kanzow, 1999, Lemma 6.1). *Suppose that $0 \leq a < b$ are chosen such the conditions*

$$\psi(a) \leq 0 \quad \text{and} \quad \psi'(a) < 0 \quad (5.19a)$$

$$\text{as well as} \quad \psi(b) \geq 0 \quad (5.19b)$$

hold; see Figure 5.4. Then there exists $\alpha^* \in (a, b)$ such that

$$\psi(\alpha^*) < 0 \quad \text{and} \quad \psi'(\alpha^*) = 0$$

holds. In particular, the Wolfe-Powell conditions (5.12') and (5.17') hold in a neighborhood of α^* .

Proof. Let us denote by α^* a global minimizer of

Minimize $\psi(\alpha)$ on the compact interval $[a, b]$.

The assumptions on a and b imply that α^* belongs to the open interval (a, b) . Consequently, α^* is also a local minimizer of the unconstrained problem “Minimize $\psi(\alpha)$ where $\alpha \in \mathbb{R}$ ”, and thus we have $\psi'(\alpha^*) = 0$. From $\psi(a) \leq 0$ and $\psi'(a) < 0$ we infer $\psi(\alpha^*) < 0$. Since both (5.12') and (5.17') hold with strict inequalities at α^* , continuity implies that they hold in a neighborhood of α^* . \square

Figure 5.4: Illustration of the condition (5.19) and the statement of Lemma 5.17.

Note: The condition (5.19a) is readily seen to hold at $a = 0$. This motivates the strategy to first find a right boundary b so that (5.19b) holds as well, and then to approximate α^* by nesting intervals.

Algorithm 5.18 (Wolfe-Powell line search).

Input: initial trial step size α

Input: routine to evaluate φ and φ'

Input: pre-computed function values $\varphi(0)$ and $\varphi'(0)$

Input: Armijo and curvature parameters $0 < \sigma < \tau < 1$

Input: expansion parameter $\gamma > 1$

Input: nesting parameters $\underline{\gamma}, \bar{\gamma} \in (0, 1/2]$

Output: step size α satisfying the Wolfe-Powell conditions (5.12) and (5.17)

1: Set $a := 0$ and $b := \alpha$

2: Set $\ell := 0$

3: **while** $\varphi(b) < \varphi(0) + \sigma \varphi'(0) b$ and $\varphi'(b) < \tau \varphi'(0)$ **do** // phase 1 repeatedly expands $[0, b]$ until (5.19) holds

```

4:   Set  $b := \gamma b$  // expand the right boundary  $b$ 
5:   Set  $\ell := \ell + 1$ 
6: end while // now we have (5.19)
7: Set  $\alpha := b$ 
8: while Armijo condition (5.12) or curvature condition (5.17) is violated at  $\alpha$  do // phase 2 repeatedly
   shrinks  $[a, b]$  until (5.12) and (5.17) hold
9:   Choose  $\alpha \in [a + \bar{\gamma}(b - a), b - \bar{\gamma}(b - a)]$  // for instance, choose the midpoint
10:  if  $\varphi(\alpha) \geq \varphi(0) + \sigma \varphi'(0) \alpha$  then // Armijo condition is violated at  $\alpha$ 
11:    Set  $b := \alpha$  // reduce the right boundary  $b$ 
12:  else
13:    Set  $a := \alpha$  // increase the left boundary  $a$ 
14:  end if
15:  Set  $\ell := \ell + 1$ 
16: end while
17: return  $\alpha$ 

```

Remark 5.19 (on Algorithm 5.18, compare Remark 5.12).

- (i) The Armijo parameter is often chosen to be small, e. g., $\sigma = 10^{-2}$ or even $\sigma = 10^{-4}$. Depending on the characteristics of the outer method (which determines the search directions), the curvature parameter $\tau > \sigma$ should be chosen “small” as well, e. g., $\tau = 0.1$, or otherwise “large”, e. g., $\tau = 0.9$.
- (ii) Each iteration of phase 1 “costs” one additional evaluation of φ and φ' , i. e., one additional evaluation of f and f' , or rather the directional derivative of f in the direction of the current search direction; compare (5.13). Each iteration of phase 2 “costs” one additional evaluation of φ .
- (iii) Using Lemma 5.17, it is not difficult to see that Algorithm 5.18 terminates after finitely many steps under the conditions of Lemma 5.16:
 - The while loop beginning at Line 3 terminates, since for b sufficiently large, the Armijo condition (5.12) is violated. For such b , we have $\psi(b) > 0$, i. e., (5.19b) holds.
 - At the first iteration of the while loop beginning at Line 8, the conditions (5.19) of Lemma 5.17 are satisfied. Consequently, they continue to hold also in all subsequent iterations.
 - The length of the intervals $[a, b]$ in phase 2 goes to zero if infinitely many iterations of the while loop beginning at Line 8 were performed. However, as shown in Lemma 5.17, there is an open set of points which satisfy both the Armijo condition (5.12) and the curvature condition (5.17) inside any of the intervals $[a, b]$ considered in phase 2. Therefore, phase 2 must terminate.
- (iv) The step size accepted by Algorithm 5.18 may be larger or smaller than the initial trial step size provided by the user.
- (v) As was already noted for the Armijo backtracking line search (Algorithm 5.11) in Remark 5.12, in a practical implementation, one often adds further checks and stopping criteria to Algorithm 5.11.

For instance, we need to safeguard against $\varphi'(0) \geq 0$ (d is not a descent direction) and against too many unsuccessful trial steps.

- (vi) An algorithm for the strong Wolfe-Powell line search can be found in [Geiger, Kanzow, 1999](#), Kapitel 6.3.

The admissibility of step sizes generated by the Wolfe-Powell line search algorithm is shown in the following result. Clearly, this result also applies to step sizes satisfying the strong Wolfe-Powell conditions.

Lemma 5.20 (Wolfe-Powell line search produces admissible step sizes). *Suppose that [Algorithm 5.2](#) generates an infinite sequence of iterates $x^{(k)}$ and search (descent) directions $d^{(k)} \neq 0$. Suppose moreover that the step sizes $\alpha^{(k)}$ are chosen so that they satisfy the Wolfe-Powell conditions (5.12) and (5.17) (for instance by [Algorithm 5.18](#)).²³ Assume that $K \subseteq \mathbb{N}_0$ is an infinite index set such that the subsequence $(x^{(k)})_{k \in K}$ is bounded. Then the step sizes $(\alpha^{(k)})_{k \in K}$ are admissible.*

Proof. As in the proof of [Lemma 5.13](#) we obtain the result

$$-\alpha^{(k)} f'(x^{(k)}) d^{(k)} \rightarrow 0. \quad (*)$$

It remains to show

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|} \xrightarrow{k \in K} 0.$$

To this end, let $\varepsilon > 0$.

Just like in the proof of [Lemma 5.13](#), we can argue that the boundedness of $(x^{(k)})_{k \in K}$ entails that the continuous function f' is uniformly continuous “near the $(x^{(k)})_{k \in K}$ ”. More precisely, there exists $\delta > 0$ such that

$$\|f'(x^{(k)} + e) - f'(x^{(k)})\|_{M^{-1}} \leq (1 - \tau) \varepsilon \quad \text{for all } k \in K, \|e\|_M \leq \delta.$$

Because of (*), there exists an index $k_0 \in \mathbb{N}$ such that

$$\alpha^{(k)} |f'(x^{(k)}) d^{(k)}| \leq \varepsilon \delta \quad \text{for all } k \geq k_0. \quad (**)$$

From now on, let $k \in K$, $k \geq k_0$, be arbitrary. Similarly as in the proof of [Lemma 5.13](#), we consider the following cases:

Case 1: $\alpha^{(k)} \|d^{(k)}\|_M \geq \delta$

²³Notice that, in contrast to condition (5.14) in [Lemma 5.13](#), there is no lower bound on the initial trial step size necessary to be observed.

Precisely as in the proof of [Lemma 5.13](#), we obtain

$$\begin{aligned}
0 &\leq \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} && \text{since } d^{(k)} \text{ is a descent direction} \\
&= \frac{-\alpha^{(k)} f'(x^{(k)}) d^{(k)}}{\alpha^{(k)} \|d^{(k)}\|_M} \\
&\leq \frac{\varepsilon \delta}{\delta} && \text{by (**) and the assumption in case 1} \\
&= \varepsilon.
\end{aligned}$$

Case 2: $\alpha^{(k)} \|d^{(k)}\|_M < \delta$

In this we argue with the satisfaction of the curvature condition (5.17) for $\alpha^{(k)}$:

$$\tau f'(x^{(k)}) d^{(k)} \leq f'(x^{(k)} + \alpha^{(k)} d^{(k)}) d^{(k)}.$$

The addition of $|f'(x^{(k)}) d^{(k)}| = -f'(x^{(k)}) d^{(k)}$ on both sides yields

$$\begin{aligned}
(1 - \tau) |f'(x^{(k)}) d^{(k)}| &\leq f'(x^{(k)} + \alpha^{(k)} d^{(k)}) d^{(k)} - f'(x^{(k)}) d^{(k)} \\
&\leq |f'(x^{(k)} + \alpha^{(k)} d^{(k)}) d^{(k)} - f'(x^{(k)}) d^{(k)}| \\
&\leq \|f'(x^{(k)} + \alpha^{(k)} d^{(k)}) - f'(x^{(k)})\|_{M^{-1}} \|d^{(k)}\|_M.
\end{aligned}$$

Invoking now the uniform continuity, we obtain

$$(1 - \tau) |f'(x^{(k)}) d^{(k)}| \leq (1 - \tau) \varepsilon \|d^{(k)}\|_M,$$

and hence

$$0 \leq \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \leq \varepsilon.$$

□

Analogously as with the Armijo backtracking line search ([Remark 5.14](#)), one can also show the efficiency of step sizes when f' is Lipschitz continuous on the sublevel set $\mathcal{M}_f(x^{(0)}) := \{x \in \mathbb{R}^n \mid f(x) \leq f(x^{(0)})\}$. The proof is part of [homework problem 4.2](#).

In concluding, we also remark that [Line 9](#) in phase 2 of [Algorithm 5.18](#) leaves some freedom in the choice of the next trial step size α . The available data $\varphi(a)$, $\varphi'(a)$, $\varphi(b)$ and $\varphi'(b)$ lends itself to a cubic Hermite interpolation, using the model

$$p(\alpha) = a + b\alpha + c\alpha^2 + d\alpha^3.$$

Provided that a unique local minimizer α^* of p exists, we can calculate it explicitly and subsequently clip it to the interval $[a, b]$:

$$\alpha := \max\{a, \min\{b, \alpha^*\}\}.$$

One needs to pay attention to the fact that not all of the data $\varphi'(a)$ and $\varphi'(b)$ is necessarily available in the current iteration of [Algorithm 5.18](#). In this case one may proceed with a quadratic polynomial as in the modified Armijo backtracking line search method.

Remark 5.21 (Scaling invariance of the Armijo and curvature conditions). *The Armijo and curvature conditions (5.12), (5.17) and (5.18) are invariant w.r.t. affine scaling in the domain and codomain spaces. Suppose that we consider, besides the objective f , another objective g related via*

$$f(x) \rightsquigarrow g(x) := \gamma f(Ax + b) + \delta,$$

where $A \in \mathbb{R}^{n \times n}$ is non-singular, $b \in \mathbb{R}^n$, $\gamma > 0$ and $\delta \in \mathbb{R}$.

Then the following holds: a step size α that satisfies any of the conditions (5.12), (5.17) or (5.18) for g at x with search direction d , satisfies the same conditions for f at $Ax + b$ with the search direction Ad . Since the scaling of an optimization problem is often arbitrary, this is a desirable property.

The proof is part of [homework problem 4.3](#).

§ 5.3 GRADIENT DESCENT METHOD

In the remainder of § 5 we consider different concrete realizations of the generic descent method [Algorithm 5.2](#). The methods differ w.r.t. the way the search directions $d^{(k)}$ are generated and w.r.t. the choice of the line search method (Armijo or Wolfe-Powell) to determine the step sizes $\alpha^{(k)}$. As was already mentioned, the methods discussed here obtain the search direction at an iterate $x^{(k)}$ by minimizing a quadratic model of the objective

$$q^{(k)}(d) = f(x^{(k)}) + f'(x^{(k)})d + \frac{1}{2}d^T H^{(k)}d. \quad (5.2)$$

When the model Hessian $H^{(k)}$ is s. p. d., this is equivalent to the solution of the linear system

$$H^{(k)}d^{(k)} = -\nabla f(x^{(k)}). \quad (5.4)$$

The **gradient descent method** (also known as **steepest descent method**) for our generic unconstrained linear problem

$$\text{Minimize } f(x) \quad \text{where } x \in \mathbb{R}^n \quad (\text{UP})$$

generates its search directions in the same way we already know from § 4.2, when f was a quadratic polynomial. That is, we use

$$Md^{(k)} = -\nabla f(x^{(k)}) \quad \text{or} \quad d^{(k)} = -M^{-1}\nabla f(x^{(k)}) = -\nabla_M f(x^{(k)}). \quad (5.20)$$

This corresponds to using a constant model Hessian $H^{(k)} \equiv M$ in the model (5.2):

$$q^{(k)}(d) = f(x^{(k)}) + f'(x^{(k)})d + \frac{1}{2}d^T M d.$$

The choice of the inner product M is due to the user. As was already mentioned in [Remark 4.7](#), one refers to the case $M = \text{Id}$ as the classical **gradient descent method** without preconditioning. Otherwise one speaks of a **preconditioned gradient descent method** with **preconditioner** M .

The particular choice of $d^{(k)}$ in the gradient descent method clearly implies the angle condition (5.8) with the maximal possible value, $\eta = 1$. In particular, the search direction $d^{(k)}$ is a descent direction for f at $x^{(k)}$, as long as $f'(x^{(k)}) \neq 0$ holds.

A simple strategy is sufficient to determine admissible step sizes (5.10). One typically employs the Armijo backtracking line search (Algorithm 5.11) or the version with interpolation (Algorithm 5.15).

The efficiency condition (5.15) requires that the initial trial step size satisfy

$$\begin{aligned}\alpha^{(k,0)} &\geq c \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M^2} \\ &= c \frac{-(\nabla_M f(x^{(k)}), d^{(k)})_M}{\|d^{(k)}\|_M^2} \\ &= c \frac{\|d^{(k)}\|_M^2}{\|d^{(k)}\|_M^2} \quad \text{since } d^{(k)} = -\nabla_M f(x^{(k)}) \\ &= c\end{aligned}$$

with some constant $c > 0$. This simply suggests to impose a lower bound on the initial trial step sizes in gradient descent methods. We will re-label c as $\underline{\alpha}$ in Algorithm 5.22 below.

In addition to observing this bound, it is useful to construct initial trial step sizes using information from past iterations. Assuming that the descent achievable in the current step is equal (to first order) to the descent in the previous step (when the accepted step size was $\alpha^{(k-1)}$), we obtain the following proposal for an initial trial step size $\alpha^{(k,0)}$ at iteration $k \geq 1$:

$$\begin{aligned}\alpha^{(k,0)} f'(x^{(k)}) d^{(k)} &= \alpha^{(k-1)} f'(x^{(k-1)}) d^{(k-1)} \\ \Rightarrow \alpha^{(k,0)} &= \alpha^{(k-1)} \frac{f'(x^{(k-1)}) d^{(k-1)}}{f'(x^{(k)}) d^{(k)}}.\end{aligned}$$

Plugging in the descent directions used in the gradient descent method, this becomes

$$\alpha^{(k,0)} = \alpha^{(k-1)} \frac{\|\nabla_M f(x^{(k-1)})\|_M^2}{\|\nabla_M f(x^{(k)})\|_M^2} = \alpha^{(k-1)} \frac{\|d^{(k-1)}\|_M^2}{\|d^{(k)}\|_M^2}.$$

Alternatively, we could use the actual descent achieved in the previous step instead of its linearization, which would result in

$$\alpha^{(k,0)} = \frac{f(x^{(k-1)}) - f(x^{(k)})}{\|\nabla_M f(x^{(k)})\|_M^2} = \frac{f(x^{(k-1)}) - f(x^{(k)})}{\|d^{(k)}\|_M^2}.$$

We state the full gradient descent method in Algorithm 5.22, using the above considerations for the initial trial step size. As was the case for our methods in § 4 addressing the minimization of quadratic polynomials, we refer to the value of the derivative of f at an iterate $x^{(k)}$ as the **residual** $r^{(k)}$.

The global convergence of Algorithm 5.22, in the sense that every accumulation point of the sequence of iterates $x^{(k)}$ is a stationary point, follows directly from the [global convergence theorem 5.9](#).

Algorithm 5.22 (Gradient descent method for (UP) w.r.t. the M -inner product and Armijo backtracking line search).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Input: Armijo parameter $\sigma \in (0, 1)$ // to be passed through to the Armijo backtracking line search

Input: backtracking parameter $\beta \in (0, 1)$ // to be passed through to the Armijo backtracking line search

Input: lower bound $\underline{\alpha} > 0$ for the initial trial step sizes

Output: approximately stationary point of (UP)

```

1: Set  $k := 0$ 
2: Set  $f^{(0)} := f(x^{(0)})$  // evaluate the initial objective value
3: Set  $r^{(0)} := f'(x^{(0)})^\top = \nabla f(x^{(0)})$  // evaluate the initial residual
4: Set  $d^{(0)} := -M^{-1}r^{(0)}$ 
5: Set  $\delta^{(0)} := -(r^{(0)})^\top d^{(0)}$  //  $\delta^{(0)} = \|\nabla_M f(x^{(0)})\|_M^2 = \|d^{(0)}\|_M^2$ 
6: while stopping criterion not met do
7:   if  $k = 0$  then
8:     Set  $\alpha^{(k,0)} := \underline{\alpha}$  // no information from previous iteration available
9:   else
10:    Set  $\alpha^{(k,0)} := \max\{\underline{\alpha}, \frac{f^{(k-1)} - f^{(k)}}{\delta^{(k)}}\}$ 
11:   end if
12:   Determine a step size  $\alpha^{(k)} > 0$  from an Armijo backtracking line search procedure (Algorithm 5.11),
   applied to  $\varphi(\alpha) := f(x^{(k)} + \alpha d^{(k)})$ , with initial trial step size  $\alpha^{(k,0)}$ , Armijo parameter  $\sigma$  and
   backtracking parameter  $\beta$  //  $\varphi(0) = f^{(k)}$  and  $\varphi'(0) = (r^{(k)})^\top d^{(k)} = -\delta^{(k)}$  are already known
13:   Set  $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$ 
14:   Set  $f^{(k+1)} := f(x^{(k+1)})$  // can be returned by the Armijo backtracking line search routine
15:   Set  $r^{(k+1)} := f'(x^{(k+1)})^\top = \nabla f(x^{(k+1)})$ 
16:   Set  $d^{(k+1)} := -M^{-1}r^{(k+1)}$ 
17:   Set  $\delta^{(k+1)} := -(r^{(k+1)})^\top d^{(k+1)}$  //  $\delta^{(k+1)} = \|\nabla_M f(x^{(k+1)})\|_M^2 = \|d^{(k+1)}\|_M^2$ 
18:   Set  $k := k + 1$ 
19: end while
20: return  $x^{(k)}$ 

```

In Line 12, we could also invoke the modified Armijo backtracking method (Algorithm 5.15), with the backtracking parameter β replaced by the pair of parameters $0 < \underline{\beta} < \bar{\beta} < 1$.

As a stopping criterion, we can choose again any of the conditions from (4.14), i. e., stop on the relative or absolute magnitude of the derivative or gradient

$$\|r^{(k)}\|_{M^{-1}} = \|f'(x^{(k)})\|_{M^{-1}} = \|\nabla_M f(x^{(k)})\|_M = \|d^{(k)}\|_M = (\delta^{(k)})^{1/2}.$$

These quantities are already available in the algorithm. A limited interpretation in the sense of Lemma 4.11 is also possible. In case the sequence $x^{(k)}$ converges to a local minimizer that satisfies the second-order sufficient optimality condition (Theorem 3.3), then we have: for all $\varepsilon > 0$, there exists $\delta > 0$ such that

$$\|x^{(k)} - x^*\|_M \leq \delta \quad \text{and} \quad \|f'(x^{(k)})\|_{M^{-1}} \leq \varepsilon_{\text{abs}} \quad \Rightarrow \quad \|x^{(k)} - x^*\|_M \leq \underbrace{\left(\frac{1}{\alpha} + \varepsilon\right)}_{\approx 1/\alpha} \varepsilon_{\text{abs}},$$

where $\alpha = \lambda_{\min}(f''(x^*); M)$ is the smallest eigenvalue of the Hessian at the solution w.r.t. M . In other words, when we are sufficiently close to a local minimizer satisfying the second-order sufficient optimality condition, then the norm of the derivative (or the gradient) is — up to the factor $1/\alpha$ — a useful measure of the distance to the solution.

Other often used stopping criteria are

$$\begin{aligned}\|x^{(k)} - x^{(k-1)}\|_M &\leq \varepsilon_{\text{abs}}^x + \varepsilon_{\text{rel}}^x \|x^{(k)} - x^{(0)}\|_M, \\ |f(x^{(k)}) - f(x^{(k-1)})| &\leq \varepsilon_{\text{abs}}^f + \varepsilon_{\text{rel}}^f |f(x^{(k)}) - f(x^{(0)})|.\end{aligned}$$

These are triggered by slow progress in the iterates or the objective values, respectively. One typically sets $\varepsilon_{\text{rel}}^f = (\varepsilon_{\text{rel}}^x)^2$.

It is remarkable that it is possible to monitor the quantities $\|x^{(k)} - x^{(k-1)}\|_M$ and $\|x^{(k)} - x^{(0)}\|_M$, although the matrix M (or matrix-vector products with M) may not be available. Matrix-vector products with M^{-1} are sufficient. The following quantities are useful for this purpose and can be recursively updated, compare (4.33):

$$\omega^{(k)} := \|x^{(k)} - x^{(0)}\|_M^2 \quad (5.21a)$$

$$\xi^{(k)} := (x^{(k)} - x^{(0)})^\top M d^{(k)} = -(x^{(k)} - x^{(0)})^\top r^{(k)} \quad (5.21b)$$

$$\delta^{(k)} := \|d^{(k)}\|_M^2 \quad (5.21c)$$

The details are left as an exercise.

End of Week 4

§ 5.4 NEWTON'S METHOD

Newton's method is known as a method to solve a (nonlinear) equation $F(x) = 0$, where $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function. For optimization purposes, we apply it to the first-order necessary optimality condition, i. e., we have $F(x) = \nabla f(x) = 0$, and thus f is assumed to be of class C^2 .

The idea of Newton's method to find a zero (root) of F is as follows. Suppose $x^{(0)}$ is an initial guess. We replace F by its linear Taylor model at $x^{(0)}$ and determine the zero of this model instead. This results in

$$F(x^{(0)}) + F'(x^{(0)})(x - x^{(0)}) = 0 \quad \Leftrightarrow \quad x = x^{(0)} - F'(x^{(0)})^{-1}F(x^{(0)}),$$

provided that the Jacobian $F'(x^{(0)})$ is non-singular. This zero of the linear model is used as the next iterate $x^{(1)}$, etc. This procedure is known as the **(local) Newton's method**.

Algorithm 5.23 (Local Newton's method for $F(x) = 0$).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate F and F'

Output: approximate zero of F

1: Set $k := 0$

- 2: **while** stopping criterion not met **do**
 3: Determine the **Newton direction** by solving

$$F'(x^{(k)}) d^{(k)} = -F(x^{(k)})$$

- 4: Set $x^{(k+1)} := x^{(k)} + d^{(k)}$
 5: Set $k := k + 1$
 6: **end while**
 7: **return** $x^{(k)}$

AUXILIARY RESULTS

We recall some auxiliary results, which you may know from *Grundlagen der Optimierung* (Herzog, 2022) or other classes. As usual, we equip \mathbb{R}^n with the M -inner product. Recall from § 2.2 that the operator norm of a matrix $K \in \mathbb{R}^{n \times n}$ that represents a map $K: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is defined by

$$\|K\|_{M \leftarrow M} := \max_{x \neq 0} \frac{\|Kx\|_M}{\|x\|_M}.$$

Although in finite dimensions all norms are equivalent, the above norm is not always the most appropriate choice: some matrices $A \in \mathbb{R}^{n \times n}$ actually represent maps $A: \mathbb{R}^n \rightarrow (\mathbb{R}^n)^*$, where $(\mathbb{R}^n)^*$ is the dual space of \mathbb{R}^n . The appropriate inner product in the dual space is the M^{-1} -inner product, leading to

$$\|A\|_{M^{-1} \leftarrow M} := \max_{x \neq 0} \frac{\|Ax\|_{M^{-1}}}{\|x\|_M}.$$

Consequently, we would use

$$\|A^{-1}\|_{M \leftarrow M^{-1}} := \max_{r \neq 0} \frac{\|A^{-1}r\|_M}{\|r\|_{M^{-1}}}$$

for the inverse of A . We also need the case $B: (\mathbb{R}^n)^* \rightarrow \mathbb{R}^n$.

Lemma 5.24 (Banach' lemma).

- (i) Suppose that $K \in \mathbb{R}^{n \times n}$ is a matrix $\|K\|_{M \leftarrow M} < 1$. Then $\text{Id} - K$ is non-singular, and we have the following estimate on the norm of its inverse:

$$\|(\text{Id} - K)^{-1}\|_{M \leftarrow M} \leq \frac{1}{1 - \|K\|_{M \leftarrow M}}.$$

- (ii) Suppose that $A, B \in \mathbb{R}^{n \times n}$ are such that $\|\text{Id} - BA\|_{M \leftarrow M} < 1$. Then A and B are both non-singular, and we have

$$\|B^{-1}\|_{M^{-1} \leftarrow M} \leq \frac{\|A\|_{M^{-1} \leftarrow M}}{1 - \|\text{Id} - BA\|_{M \leftarrow M}} \quad \text{und} \quad \|A^{-1}\|_{M \leftarrow M^{-1}} \leq \frac{\|B\|_{M \leftarrow M^{-1}}}{1 - \|\text{Id} - BA\|_{M \leftarrow M}}.$$

Note: Statement (i) states that “small” perturbations of the identity matrix are still invertible. Statement (ii) states that $\text{Id} - BA$ “small”, i. e., $B \approx A^{-1}$, entails that A and B are both necessarily invertible.

Proof. **Statement (i):** For $x \in \mathbb{R}^n$, we have

$$\begin{aligned} \|(\text{Id} - K)x\|_M &= \|x - Kx\|_M \\ &\geq \|x\|_M - \|Kx\|_M && \text{by the triangle inequality} \\ &\geq \underbrace{(1 - \|K\|_{M \leftarrow M})}_{>0} \|x\|_M && \text{since } \|Kx\|_M \leq \|K\|_{M \leftarrow M} \|x\|_M. \end{aligned}$$

This implies $(\text{Id} - K)x \neq 0$ for $x \neq 0$, ie, $\text{Id} - K$ is injective and thus non-singular.

Now let $y \in \mathbb{R}^n$ be arbitrary and $x := (\text{Id} - K)^{-1}y$. Then the above estimate shows

$$\begin{aligned} \|y\|_M &\geq (1 - \|K\|_{M \leftarrow M}) \|(\text{Id} - K)^{-1}y\|_M \\ \Rightarrow \|(\text{Id} - K)^{-1}\|_{M \leftarrow M} &= \max_{y \neq 0} \frac{\|(\text{Id} - K)^{-1}y\|_M}{\|y\|_M} \leq \frac{1}{1 - \|K\|_{M \leftarrow M}}. \end{aligned}$$

Statement (ii): We set $K := \text{Id} - BA$, whence $\|K\|_{M \leftarrow M} < 1$ holds. Due to **Statement (i)**, we find that $\text{Id} - K = \text{Id} - (\text{Id} - BA) = BA$ is non-singular, i. e., A and B are both non-singular. Moreover,

$$\begin{aligned} (\text{Id} - K)^{-1} &= (BA)^{-1} = A^{-1}B^{-1} \\ \Rightarrow B^{-1} &= A(\text{Id} - K)^{-1} \\ \Rightarrow \|B^{-1}\|_{M^{-1} \leftarrow M} &\leq \|A\|_{M^{-1} \leftarrow M} \|(\text{Id} - K)^{-1}\|_{M \leftarrow M} \\ &\leq \frac{\|A\|_{M^{-1} \leftarrow M}}{1 - \|K\|_{M \leftarrow M}} && \text{by Statement (i)} \\ &= \frac{\|A\|_{M^{-1} \leftarrow M}}{1 - \|\text{Id} - BA\|_{M \leftarrow M}}. \end{aligned}$$

The remaining inequality follows similarly. □

Lemma 5.25 (Implications of the invertibility of the Jacobian). *Suppose that $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function and that $x^* \in \mathbb{R}^n$ is arbitrary with non-singular Jacobian $F'(x^*)$.*

(i) *Then there exists a neighborhood $B_\delta^M(x^*)$ and a constant $c > 0$ such that $F'(x)$ is invertible for all $x \in B_\delta^M(x^*)$. Moreover,*

$$\|F'(x)^{-1}\|_{M \leftarrow M^{-1}} \leq c \quad \text{holds for all } x \in B_\delta^M(x^*). \quad (5.22)$$

(ii) *Suppose now in addition that $F(x^*) = 0$ holds. Then there exist a neighborhood $B_\delta^M(x^*)$ and a constant $\beta > 0$ such that*

$$\|x - x^*\|_M \leq \beta \|F(x)\|_{M^{-1}} \quad \text{for all } x \in B_\delta^M(x^*). \quad (5.23)$$

β can be chosen as $2 \|F'(x^)^{-1}\|_{M \leftarrow M^{-1}}$.*

Note: **Statement (i)** is an instance of the fact from functional analysis that the set of boundedly invertible linear operators between two Banach spaces is open. **Statement (ii)** allows us to estimate the norm of the error $\|x - x^*\|_M$ from the norm of the residual $\|F(x)\|_{M^{-1}}$.

Proof. **Statement (i):** Since F' is continuous at x^* , there exists $\delta > 0$ such that

$$\|F'(x^*) - F'(x)\|_{M^{-1} \leftarrow M} \leq \varepsilon := \frac{1}{2 \|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}}}$$

holds for all $x \in B_\delta^M(x^*)$. Consequently,

$$\begin{aligned} \|\text{Id} - F'(x^*)^{-1} F'(x)\|_{M \leftarrow M} &= \|F'(x^*)^{-1} (F'(x^*) - F'(x))\|_{M \leftarrow M} \\ &\leq \|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}} \|F'(x^*) - F'(x)\|_{M^{-1} \leftarrow M} \\ &\leq \frac{1}{2} < 1. \end{aligned}$$

By **Statement (ii)** of **Lemma 5.24** [with $A = F'(x)$ and $B = F'(x^*)^{-1}$], we can conclude that $F'(x)$ is non-singular for all $x \in B_\delta^M(x^*)$ with

$$\|F'(x)^{-1}\|_{M \leftarrow M^{-1}} \leq \frac{\|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}}}{1 - \|\text{Id} - F'(x^*)^{-1} F'(x)\|_{M \leftarrow M}} \leq 2 \|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}} =: c.$$

Statement (ii): Since F is differentiable in x^* , there exists — for the same $\varepsilon > 0$ as above — a $\delta > 0$ such that

$$\|F(x) - F(x^*) - F'(x^*)(x - x^*)\|_{M^{-1}} \leq \varepsilon \|x - x^*\|_M \quad \text{for all } x \in B_\delta^M(x^*).$$

Therefore, for all $x \in B_\delta^M(x^*)$,

$$\begin{aligned} \|F(x)\|_{M^{-1}} &\geq \|F'(x^*)(x - x^*)\|_{M^{-1}} - \overbrace{\|F(x) - F(x^*) - F'(x^*)(x - x^*)\|_{M^{-1}}}^{=0} \quad \text{by the triangle inequality.} \end{aligned}$$

In view of $\|x - x^*\|_M = \|F'(x^*)^{-1} F'(x^*)(x - x^*)\|_M \leq \|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}} \|F'(x^*)(x - x^*)\|_{M^{-1}}$, we can estimate this by

$$\begin{aligned} \|F(x)\|_{M^{-1}} &\geq \frac{1}{\|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}}} \|x - x^*\|_M - \varepsilon \|x - x^*\|_M \\ &= \varepsilon \|x - x^*\|_M \quad \text{by the definition of } \varepsilon, \end{aligned}$$

and the claim follows with $\beta = \varepsilon^{-1}$. □

Lemma 5.26 (Auxiliary estimate). *Suppose that $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function and $x^* \in \mathbb{R}^n$. For all $\varepsilon > 0$, there exists $\delta > 0$ such that*

$$\|F(x) - F(x^*) - F'(\textcolor{red}{x})(x - x^*)\|_{M^{-1}} < \varepsilon \|x - x^*\|_M$$

holds for all $x \in B_\delta^M(x^)$.*²⁴

²⁴Briefly, we can also denote this result as $\|F(x) - F(x^*) - F'(\textcolor{red}{x})(x - x^*)\|_M \in o(\|x - x^*\|_M)$.

Proof. Take $\varepsilon > 0$. The triangle inequality implies

$$\begin{aligned} & \|F(x) - F(x^*) - F'(\bar{x})(x - x^*)\|_{M^{-1}} \\ & \leq \|F(x) - F(x^*) - F'(\bar{x}^*)(x - x^*)\|_{M^{-1}} + \|F'(\bar{x}^*) - F'(\bar{x})\|_{M^{-1} \leftarrow M} \|x - x^*\|_M. \end{aligned}$$

Since by assumption, F is differentiable in x^* , there exists $\delta_1 > 0$ such that

$$\|F(x) - F(x^*) - F'(\bar{x}^*)(x - x^*)\|_{M^{-1}} < \frac{\varepsilon}{2} \|x - x^*\|_M$$

holds for all $x \in B_{\delta_1}^M(x^*)$. On the other hand, F' is continuous in x^* , which implies the existence of $\delta_2 > 0$ such that

$$\|F'(\bar{x}^*) - F'(\bar{x})\|_{M^{-1}} < \frac{\varepsilon}{2}$$

holds for all $x \in B_{\delta_2}^M(x^*)$. The conclusion follows with $\delta := \min\{\delta_1, \delta_2\}$. \square

LOCAL NEWTON'S METHOD FOR $F(x) = 0$

We are now in a position to prove a convergence theorem for local Newton's method.

Theorem 5.27 (Convergence of local Newton's method). *Suppose that $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function and that $x^* \in \mathbb{R}^n$ is a point where $F(x^*) = 0$ and $F'(x^*)$ is non-singular. Then there exists a neighborhood $B_\delta^M(x^*)$ such that*

- (i) x^* is the unique zero of F in $B_\delta^M(x^*)$.
- (ii) For any initial guess $x^{(0)} \in B_\delta^M(x^*)$, the local Newton's method is well-defined, and it generates a sequence $x^{(k)}$ which converges to x^* .
- (iii) $(x^{(k)})$ converges to x^* Q -superlinearly w.r.t. the M -norm.
- (iv) If F' is Lipschitz continuous in $B_\delta^M(x^*)$, then this convergence is even Q -quadratic.

Proof. **Statement (i):** By **Statement (ii)** of **Lemma 5.25**, there exists $\delta_0 > 0$ such that x^* is the only zero of F in $B_{\delta_0}^M(x^*)$.

Statement (ii): By **Statement (i)** of **Lemma 5.25**, there exist $\delta_1 > 0$ and $c > 0$ such that $F'(x)$ is non-singular for all $x \in B_{\delta_1}^M(x^*)$ and

$$\|F'(x)^{-1}\|_{M \leftarrow M^{-1}} \leq c := 2 \|F'(x^*)^{-1}\|_{M \leftarrow M^{-1}}. \quad (*)$$

By **Lemma 5.26**, given $\varepsilon = 1/(2c)$, there exists $\delta_2 > 0$ such that

$$\|F(x) - F(x^*) - F'(x)(x - x^*)\|_{M^{-1}} \leq \frac{1}{2c} \|x - x^*\|_M$$

holds for all $x \in B_{\delta_2}^M(x^*)$. Now set $\delta := \min\{\delta_0, \delta_1, \delta_2\}$ and choose $x^{(0)} \in B_\delta^M(x^*)$ arbitrarily. Then the next iterate $x^{(1)} := x^{(0)} - F'(x^{(0)})^{-1}F(x^{(0)})$ is well-defined, and we have

$$\begin{aligned} \|x^{(1)} - x^*\|_M &= \|x^{(0)} - x^* - F'(x^{(0)})^{-1}F(x^{(0)})\|_M \stackrel{=0}{=} \\ &= \|F'(x^{(0)})^{-1}[F'(x^{(0)})(x^{(0)} - x^*) - \overbrace{F(x^{(0)}) - F(x^*)}^{=0}]\|_M \\ &\leq \|F'(x^{(0)})^{-1}\|_{M \leftarrow M^{-1}} \|F(x^{(0)}) - F(x^*) - F'(x^{(0)})(x^{(0)} - x^*)\|_{M^{-1}} \\ &\leq c \frac{1}{2c} \|x^{(0)} - x^*\|_M \\ &= \frac{1}{2} \|x^{(0)} - x^*\|_M, \end{aligned}$$

and thus $x^{(1)}$ again belongs to $B_\delta^M(x^*)$. By induction, $x^{(k)}$ is well-defined, it belongs to $B_\delta^M(x^*)$, and $x^{(k)} \rightarrow x^*$ Q-linearly w.r.t. the M -norm.

Statement (iii): We begin by setting up an equation for the error:

$$\begin{aligned} x^{(k+1)} - x^* &= x^{(k)} - x^* - F'(x^{(k)})^{-1}(F(x^{(k)}) - F(x^*)) \\ &= F'(x^{(k)})^{-1}[F'(x^{(k)})(x^{(k)} - x^*) - (F(x^{(k)}) - F(x^*))] \\ &= F'(x^{(k)})^{-1}\left[F'(x^{(k)})(x^{(k)} - x^*) - \int_0^1 F'(x^{(k)} + t(x^* - x^{(k)}))(x^{(k)} - x^*) dt\right] \\ &= F'(x^{(k)})^{-1}\left[\int_0^1 F'(x^{(k)}) - F'(x^{(k)} + t(x^* - x^{(k)})) dt\right](x^{(k)} - x^*). \end{aligned}$$

This gives us the following fundamental estimate:

$$\begin{aligned} \|x^{(k+1)} - x^*\|_M &\stackrel{=:D^{(k)}(t)}{=} \\ &\leq \|F'(x^{(k)})^{-1}\|_{M \leftarrow M^{-1}} \underbrace{\int_0^1 \|F'(x^{(k)}) - F'(x^{(k)} + t(x^* - x^{(k)}))\|_{M^{-1} \leftarrow M} dt}_{=:I^{(k)}} \|x^{(k)} - x^*\|_M. \quad (**) \end{aligned}$$

Due to $x^{(k)} \rightarrow x^*$, we infer that $x^{(k)} + t(x^* - x^{(k)}) \rightarrow x^*$ uniformly for $t \in [0, 1]$. Moreover, F' is continuous, and thus for any $\varepsilon > 0$, there exists an index $k_0 \in \mathbb{N}$ such that

$$\|D^{(k)}(t)\|_{M^{-1} \leftarrow M} \leq \varepsilon \quad \text{for all } k \geq k_0 \text{ and all } t \in [0, 1].$$

This implies

$$0 \leq I^{(k)} = \int_0^1 \|D^{(k)}(t)\|_{M^{-1} \leftarrow M} dt \leq \varepsilon \quad \text{for all } k \geq k_0.$$

This in turn gives $I^{(k)} \rightarrow 0$. But now $(*)$ and $(**)$ give us

$$\|x^{(k+1)} - x^*\|_M \leq c I^{(k)} \|x^{(k)} - x^*\|_M \leq c \varepsilon \|x^{(k)} - x^*\|_M$$

for all $k \geq k_0$, which is the Q-superlinear convergence.

Statement (iv): Since $x^{(k)}$ and $x^{(k)} + t(x^* - x^{(k)})$ belong to $B_\delta^M(x^*)$ for all $t \in [0, 1]$, we can estimate the integral in a better way, using the stronger assumptions:

$$I^{(k)} = \int_0^1 \|F'(x^{(k)}) - F'(x^{(k)} + t(x^* - x^{(k)}))\|_{M^{-1} \leftarrow M} dt \leq \int_0^1 L t \|x^* - x^{(k)}\|_M dt = \frac{L}{2} \|x^{(k)} - x^*\|_M.$$

From (**) we now obtain

$$\|x^{(k+1)} - x^*\|_M \leq c \frac{L}{2} \|x^{(k)} - x^*\|_M^2.$$

□

Remark 5.28 (on local Newton's method (Algorithm 5.23)).

- (i) *Local Newton's method (Algorithm 5.23) may break down since $F'(x^{(k)})$ is not guaranteed to be invertible, in case the initial guess $x^{(0)}$ lies outside the unknown neighborhood of local convergence $B_\delta^M(x^*)$.*
- (ii) *The **simplified Newton's method**, which uses the fixed matrix $F'(x^{(0)})$ (assumed to be invertible) instead of $F'(x^{(k)})$, still converges Q -linearly w.r.t. the M -norm.*

LOCAL NEWTON'S METHOD IN OPTIMIZATION

Newton's method in optimization can be motivated in one of two ways:

- (i) The first-order necessary optimality condition for (UP) reads

$$\nabla f(x) = 0,$$

see Theorem 3.1. When we employ Newton's method to solve this (generally nonlinear) equation $F(x) = \nabla f(x)$ with Jacobian $F'(x) = f''(x)$, we obtain the iteration

$$x^{(k+1)} = x^{(k)} - f''(x^{(k)})^{-1} \nabla f(x^{(k)}). \quad (5.24)$$

- (ii) At the current iterate $x^{(k)}$, we replace (UP) by the minimization of the quadratic model

$$q^{(k)}(d) = f(x^{(k)}) + f'(x^{(k)})d + \frac{1}{2} d^T H^{(k)} d \quad (5.2)$$

where the model Hessian is the symmetric matrix $H^{(k)} = f''(x^{(k)})$. That is, (5.2) becomes the second-order Taylor polynomial. If $H^{(k)}$ is positive definite, then the unique solution of (5.2) is characterized by the linear system

$$f''(x^{(k)}) d^{(k)} = -\nabla f(x^{(k)}).$$

When one uses the fixed step size $\alpha^{(k)} = 1$ and sets

$$x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)} = x^{(k)} + d^{(k)},$$

we obtain again the iteration (5.24).

Remark 5.29 (on local Newton's method for (UP)).

(i) [Theorem 5.27](#) proves the local Q -superlinear (or local Q -quadratic) of local Newton's method towards a stationary point x^* of f , provided that $f''(x^*)$ is non-singular. The point x^* may be a local minimizer, a local maximizer, or a saddle point of f , unless we make an assumption or have knowledge about the definiteness of $f''(x^*)$.

(ii) If $f''(x^{(k)})$ is s. p. d., then the **Newton direction** $d^{(k)}$ obtained from the **Newton system**

$$f''(x^{(k)}) d^{(k)} = -\nabla f(x^{(k)}) \quad (5.25)$$

is a descent direction for f at $x^{(k)}$, as long as $f'(x^{(k)}) \neq 0$; compare (5.9):

$$f'(x^{(k)}) d^{(k)} = -\nabla f(x^{(k)})^\top f''(x^{(k)})^{-1} \nabla f(x^{(k)}) < 0.$$

Due to the fixed step size $\alpha^{(k)} = 1$ (instead of line search), descent from iterate to iterate, i. e., $f(x^{(k+1)}) < f(x^{(k)})$, is not guaranteed when $x^{(k)}$ is still “far” from the local minimizer x^* .

(iii) Local Newton's method is invariant w.r.t. affine scaling (see [homework problem 5.1](#)). This is in contrast to the steepest descent method.

(iv) $f''(x)$ is a bilinear form accepting two directions and returning a number. Consequently, when we specify only a single direction, the resulting object becomes a linear form. It is thus appropriate to view the Hessian $f''(x)$ as a map $\mathbb{R}^n \rightarrow (\mathbb{R}^n)^*$ and to use the associated operator norm.

A GLOBALIZED NEWTON'S METHOD IN OPTIMIZATION

We now seek to globalize the local Newton's method. In order to be able to apply the [global convergence theorem 5.9](#), we require the search directions and the step sizes to be admissible. We will realize these requirements via a (generalized) angle condition and an Armijo backtracking line search. In addition, we pay attention not to disturb the local Q -superlinear convergence.

Algorithm 5.30 (Globalized Newton method for **(UP)**).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Input: routine to evaluate f'' (or matrix-vector products with f'')

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Input: globalization parameters $\eta \in (0, 1)$, $\rho > 0$ and exponent $p > 0$

Input: Armijo parameter $\sigma \in (0, 1/2)$ // to be passed through to the Armijo backtracking line search

Input: backtracking parameter $\beta \in (0, 1)$ // to be passed through to the Armijo backtracking line search

Output: approximately stationary point of **(UP)**

1: Set $k := 0$

2: Set $f^{(0)} := f(x^{(0)})$

// evaluate the initial objective value

3: Set $r^{(0)} := f'(x^{(0)})^\top = \nabla f(x^{(0)})$

// evaluate the initial residual

4: Set $d_G^{(0)} := -M^{-1}r^{(0)}$

// evaluate the negative M -gradient

5: Set $\delta^{(0)} := -(r^{(0)})^\top d_G^{(0)}$

// $\delta^{(0)} = \|\nabla_M f(x^{(0)})\|_M^2 = \|d_G^{(0)}\|_M^2$

6: **while** stopping criterion not met **do**

7: Attempt to solve the Newton system

$$f''(x^{(k)}) d_N^{(k)} = -r^{(k)} \quad (5.26)$$

8: **if** the Newton system is not solvable or not uniquely solvable **then**

9: Set $d^{(k)} := d_G^{(k)}$ *// use the steepest descent direction as fallback*

10: **else** *// Newton direction $d_N^{(k)}$ available*

11: Evaluate the generalized angle condition for the Newton direction

$$f'(x^{(k)}) d_N^{(k)} \leq -\min\{\eta, \rho \|d_G^{(k)}\|_M^p\} \|d_G^{(k)}\|_M \|d_N^{(k)}\|_M \quad (5.27)$$

12: **if true then**

13: Set $d^{(k)} := d_N^{(k)}$ *// use the Newton direction*

14: **else**

15: Set $d^{(k)} := d_G^{(k)}$ *// use the steepest descent direction as fallback*

16: **end if**

17: **end if**

18: Determine a step size $\alpha^{(k)} > 0$ from an Armijo backtracking line search procedure (Algorithm 5.11), applied to $\varphi(\alpha) := f(x^{(k)} + \alpha d^{(k)})$, with initial trial step size $\alpha^{(k,0)} = 1$, Armijo parameter σ and backtracking parameter β *// $\varphi(0) = f^{(k)}$ and $\varphi'(0) = (r^{(k)})^\top d^{(k)} = -\delta^{(k)}$ in case of $d^{(k)} = d_G^{(k)}$, or $\varphi'(0) = f'(x^{(k)}) d_N^{(k)}$ in case of $d^{(k)} = d_N^{(k)}$, are already known*

19: Set $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$

20: Set $f^{(k+1)} := f(x^{(k+1)})$ *// can be returned by the Armijo backtracking line search routine*

21: Set $r^{(k+1)} := f'(x^{(k+1)})^\top = \nabla f(x^{(k+1)})$

22: Set $d_G^{(k+1)} := -M^{-1}r^{(k+1)}$ *// evaluate the negative M-gradient*

23: Set $\delta^{(k+1)} := -(r^{(k+1)})^\top d_G^{(k+1)}$ *// $\delta^{(k+1)} = \|\nabla_M f(x^{(k+1)})\|_M^2 = \|d_G^{(k+1)}\|_M^2$*

24: Set $k := k + 1$

25: **end while**

26: **return** $x^{(k)}$

So the basic idea of Algorithm 5.30 is to use the negative M -gradient $d_G^{(k)}$ in case the Newton direction $d_N^{(k)}$ is either not available, or in case it is not a good descent direction. To decide the latter, we verify its angle with the direction of steepest descent. We know that the steepest descent direction $d = d_G^{(k)}$ satisfies the angle condition (5.8), i. e.,

$$f'(x^{(k)}) d \leq -\eta \|\nabla_M f(x^{(k)})\|_M \|d\|_M = -\eta \|d_G^{(k)}\|_M \|d\|_M$$

with the maximal possible value, $\eta = 1$. In (5.27), we require qualitatively the same condition for the Newton direction, but with some smaller value $\eta \in (0, 1)$. Moreover, as the norm of the gradient $\|d_G^{(k)}\|_M$ becomes smaller, i. e., as we get closer to being stationary, we wish to encourage the Newton direction to be used in order to enable fast local convergence. In that phase, it is no longer necessary and, in fact, disadvantageous, to limit the angle between the Newton direction and the steepest descent direction. To be concrete, we use the term $\rho \|d_G^{(k)}\|_M^p$ to determine whether we are in that phase. This explains the condition

$$f'(x^{(k)}) d \leq -\min\{\eta, \rho \|d_G^{(k)}\|_M^p\} \|d_G^{(k)}\|_M \|d\|_M$$

that we employ the check the descent quality of the Newton direction $d_N^{(k)}$ in (5.27). A range of similar conditions achieving the same goal is also conceivable; see for instance Geiger, Kanzow, 1999, Kapitel 9.2 or Ulbrich, Ulbrich, 2012, p.49.

Remark 5.31 (on globalized Newton's method (Algorithm 5.30)).

(i) The parameters ρ and p are often chosen relatively small, e. g.,

$$\rho = 10^{-6} \quad \text{and} \quad p = 10^{-1}.$$

(ii) As in our previous algorithms, we may have available the preconditioner only in the form of matrix-vector products with M^{-1} . In order to evaluate (5.27), however, we need to be able to compute $\|d_N^{(k)}\|_M$ as well, which appears to be unavailable.

There is, however, an elegant way out. If we solve the Newton system (5.24) using the CG method (Algorithm 4.17) with preconditioner M and initial guess 0, we have available by (4.33)–(4.34) the M -norm of the iterates and thus also the M -norm of the solution $d_N^{(k)}$.

Moreover, the CG method can be easily modified to accommodate the situation that the Newton system is not solvable, or not uniquely solvable. This is the case when a direction of non-positive curvature is encountered during the CG iterations, i. e., when the quantity θ in Algorithm 4.17 becomes ≤ 0 . We describe these modifications below (Algorithm 5.41) in the context of inexact Newton methods, where we also take advantage of the fact that it may not be necessary to solve (5.24) exactly.

(iii) The approach to globalization taken in Algorithm 5.30 is to reject the Newton direction if it does not exist or does not offer a sufficiently negative directional derivative, and to replace it by the steepest descent direction. There are other approaches that modify the Newton direction so that it always exists and offers sufficient descent. One can, for instance, add a multiple of the identity matrix (or rather a multiple of the preconditioner) to $f''(x^{(k)})$ when the latter is found not to be “sufficiently positive definite”. The modified Newton system then reads

$$[f''(x^{(k)}) + \tau M] d^{(k)} = -\nabla f(x^{(k)})$$

with some $\tau > 0$; see for instance Geiger, Kanzow, 1999, p.93 and Nocedal, Wright, 2006, p.51.

We now proceed to show the global convergence of Algorithm 5.30.

Theorem 5.32 (Convergence of globalized Newton's method). Suppose that f is of class C^2 . Suppose that x^* is an accumulation point of $x^{(k)}$ and that $(x^{(k)})_{k \in K}$ is a subsequence converging to x^* . Then the search directions $(d^{(k)})_{k \in K}$ and step sizes $(\alpha^{(k)})_{k \in K}$ are admissible. Consequently, we have $f'(x^*) = 0$.

Proof. We verify the prerequisites of the global convergence theorem 5.9, which then implies $f'(x^*) = 0$. To this end, we set

$$\begin{aligned} K_N &:= \{k \in K : d^{(k)} = d_N^{(k)}\} && \text{(index set of Newton steps)} \\ K_G &:= K \setminus K_N && \text{(index set of gradient steps).} \end{aligned}$$

Step (1) Wir first show the admissibility of the search directions. That is, we have to show that

$$\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \xrightarrow{k \in K} 0 \quad \text{implies} \quad f'(x^{(k)}) \xrightarrow{k \in K} 0. \quad (5.7')$$

For indices $k \in K_G$ we have $d^{(k)} = -M^{-1}\nabla f(x^{(k)})$ and thus

$$-\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} = \frac{\|\nabla_M f(x^{(k)})\|_M^2}{\|\nabla_M f(x^{(k)})\|_M} = \|\nabla_M f(x^{(k)})\|_M.$$

The left-hand side of (5.7') thus implies $\|\nabla_M f(x^{(k)})\|_M \xrightarrow{k \in K_G} 0$, which is equivalent to $f'(x^{(k)}) \xrightarrow{k \in K_G} 0$.

For the complementary indices $k \in K_N$, the generalized angle condition (5.27) reads

$$-\frac{f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \geq \min\{\eta, \rho \|d_G^{(k)}\|_M^p\} \|d_G^{(k)}\|_M \geq 0.$$

The left-hand side of (5.7') thus implies $\|d_G^{(k)}\|_M = \|\nabla_M f(x^{(k)})\|_M \xrightarrow{K_N} 0$, which is the same as $f'(x^{(k)}) \xrightarrow{k \in K_N} 0$.

Step (2) The convergence of $(x^{(k)})_{k \in K}$ and the C^2 -property of the objective imply that the subsequence of Hessians $f''(x^{(k)})$ converges as well, and consequently the subsequence $f''(x^{(k)})$ is bounded (in any norm we might impose on the space of n -by- n matrices), so that we have $\|f''(x^{(k)})\|_{M^{-1} \leftarrow M} \leq C$ for $k \in K$. For the Newton steps, we recall $f''(x) d = -\nabla f(x)$, which we can also write as $-M^{-1}f''(x) d = \nabla_M f(x)$. By the definition of matrix norms, see (2.5), we find

$$\|d^{(k)}\|_M \geq \frac{1}{\|f''(x^{(k)})\|_{M^{-1} \leftarrow M}} \|\nabla_M f(x^{(k)})\|_M \geq \frac{1}{C} \|\nabla_M f(x^{(k)})\|_M \quad \text{for } k \in K_N,$$

and clearly

$$\|d^{(k)}\|_M = 1 \|\nabla_M f(x^{(k)})\|_M \quad \text{for } k \in K_G,$$

so overall we have

$$\|d^{(k)}\|_M \geq \min\left\{\frac{1}{C}, 1\right\} \|\nabla_M f(x^{(k)})\|_M \geq \min\left\{\frac{1}{C}, 1\right\} \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \quad (5.28)$$

for all $k \in K$. In view of the initial Armijo trial step size being $\alpha^{(k,0)} = 1$, we satisfy condition (5.14) of Lemma 5.13 with $\psi(t) = \min\{t, t/C\}$, which in turn implies the admissibility of the step sizes along the subsequence.

□

Next we show that, under appropriate assumptions, Algorithm 5.30 eventually becomes identical to the local Newton's method, which means that

$$d^{(k)} = d_N^{(k)} \quad \text{and} \quad \alpha^{(k)} = 1 \quad (5.29)$$

holds for all k sufficiently large. Consequently, the local convergence theorem 5.27 applies, which yields the fast (at least Q-superlinear) convergence of the entire sequence of iterates, as soon as it is sufficiently close to a local minimizer satisfying second-order sufficient optimality condition.

Theorem 5.33 (Transition to fast local convergence in [Algorithm 5.30](#), see [Ulbrich, Ulbrich, 2012](#), Satz 10.14). Suppose that f is of class C^2 . Suppose that x^* is an accumulation point of $x^{(k)}$ and that $(x^{(k)})_{k \in K}$ is a subsequence converging to x^* . Assume, moreover, that the Hessian $f''(x^*)$ is s. p. d. Then the following holds:

- (i) $f'(x^*) = 0$ holds, i. e., x^* satisfies the second-order sufficient optimality condition.
- (ii) The entire sequence $x^{(k)}$ converges to x^* .
- (iii) There exists an index $k_0 \in \mathbb{N}_0$ such that (5.29) holds for all $k \geq k_0$. Consequently, $x^{(k)}$ converges to x^* Q -superlinearly w.r.t. the M -norm.
- (iv) If f'' is Lipschitz continuous in a neighborhood of x^* , then the convergence is Q -quadratic.

Proof. We do not provide the proof but refer the interested reader to [Ulbrich, Ulbrich, 2012](#), Satz 10.14 for the time being. \square

§ 5.5 NEWTON-LIKE METHODS

From the point of convergence analysis, the globalized Newton's method ([Algorithm 5.30](#)) is superior to the steepest descent method ([Algorithm 5.22](#)) since it offers a Q -superlinear convergence phase. However, Newton's method has a number of drawbacks as well:

- (1) The Hessian $f''(x)$ may be expensive to evaluate, and it is needed in addition to the first-order derivative $f'(x)$ of the objective.
- (2) The solution of the Newton systems

$$f''(x^{(k)}) d^{(k)} = -\nabla f(x^{(k)}) \quad (5.25)$$

is often more expensive compared to the evaluation of the gradient direction

$$M d^{(k)} = -\nabla f(d^{(k)}).$$

After all, M is constant and can be factorized using the Cholesky decomposition when the number of optimization variables is moderate.

We will address both issues simultaneously. To this end, we consider methods which allow us to

- (1) replace the Hessian $f''(x^{(k)})$ by a (s. p. d.) model Hessian $H^{(k)}$ and
- (2) solve the linear system

$$H^{(k)} d^{(k)} = -\nabla f(x^{(k)}) \quad (5.30)$$

iteratively, and possibly only inexactly.

The latter means that effectively we are solving a linear system

$$H^{(k)} d^{(k)} = -\nabla f(x^{(k)}) + \zeta^{(k)} \quad (5.31)$$

with an implicitly defined residual $\zeta^{(k)}$. To this end, we will typically specify a tolerance of the form $\|\zeta^{(k)}\|_{M^{-1}} \leq \varepsilon^{(k)}$.

As a starting point, we consider a generic local Newton-like method with no line search.

Algorithm 5.34 (Generic Newton-like method for (UP)).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Input: initial symmetric model Hessian $H^{(0)} \in \mathbb{R}^{n \times n}$ (possibly s. p. d.)

Input: routine to determine the symmetric model Hessians $H^{(k)}$ (possibly s. p. d.)

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Output: approximately stationary point of (UP)

1: Set $k := 0$ 2: **while** stopping criterion not met **do**

3: Determine a search direction $d^{(k)}$ by (inexactly) solving $H^{(k)}d^{(k)} = -\nabla f(x^{(k)})$

4: $\parallel H^{(k)} d^{(k)} = -\nabla f(x^{(k)}) + \zeta^{(k)}$ with some residual $\zeta^{(k)}$

5: *Set* $x^{(k+1)} := x^{(k)} + d^{(k)}$ 6: Determine the next model Hessian $H^{(k+1)}$

7: Set $k := k + 1$

8: *end while*9: **return** $x^{(k)}$

The following questions arise:

- (1) What are the requirements for $H^{(k)}$ and $\zeta^{(k)}$ in order to obtain fast (“Newton-like”, i. e., Q-superlinear) convergence?
- (2) What practical approaches exist to choose the matrices $H^{(k)}$ and to impose a bound for residual norm $\zeta^{(k)}$, with an eye to reducing the numerical effort?

As we did for Newton’s method (§ 5.4), we begin by considering an analog of Algorithm 5.34 to find a zero of a C^1 function $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$. In place of the exact Jacobians $F'(x^{(k)})$, we use model Jacobians $H^{(k)}$, which are supposed to be non-singular but not necessarily symmetric or positive definite.

Algorithm 5.35 (Generic Newton-like method for $F(x) = 0$).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate F

Input: routine to determine the non-singular model jacobians $H^{(k)}$

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Output: approximate zero of F

```

1: Set  $k := 0$ 
2: while stopping criterion not met do
3:   Determine a search direction  $d^{(k)}$  by (inexactly) solving  $H^{(k)} d^{(k)} = -F(x^{(k)})$ 
4:   //  $H^{(k)} d^{(k)} = -F(x^{(k)}) + \zeta^{(k)}$  with some residual  $\zeta^{(k)}$ 
5:   Set  $x^{(k+1)} := x^{(k)} + d^{(k)}$ 
6:   Set  $k := k + 1$ 
7: end while
8: return  $x^{(k)}$ 

```

In a nutshell, the sequence generated by [Algorithm 5.35](#) is governed by

$$\begin{aligned} H^{(k)} d^{(k)} &= -F(x^{(k)}) + \zeta^{(k)} \\ x^{(k+1)} &= x^{(k)} + d^{(k)}. \end{aligned} \quad (5.32)$$

The following lemma shows that the fast local convergence of any sequence $x^{(k)}$ converging to a zero of F is related to the question how well the elements of that sequence satisfy the true Newton systems $F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)}) = 0$.

Lemma 5.36 (Characterization of fast local convergence). *Suppose that $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function and that $x^{(k)}$ is any sequence in \mathbb{R}^n converging to x^* with non-singular Jacobian $F'(x^*)$. Then the following are equivalent:*

(i) $x^{(k)}$ converges Q -superlinearly w.r.t. the M -norm, and we have $F(x^*) = 0$.

(ii) For any $\varepsilon > 0$ there exists an index $k_0 \in \mathbb{N}_0$ such that²⁵

$$\|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \quad \text{for all } k \geq k_0. \quad (5.33a)$$

(iii) For any $\varepsilon > 0$ there exists an index $k_0 \in \mathbb{N}_0$ such that²⁶

$$\|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \leq \varepsilon \|x^{(k)} - x^*\|_M \quad \text{for all } k \geq k_0. \quad (5.33b)$$

(iv) For any $\varepsilon > 0$ there exists an index $k_0 \in \mathbb{N}_0$ such that²⁷

$$\|F(x^{(k)}) + F'(x^*)(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \quad \text{for all } k \geq k_0. \quad (5.33c)$$

Proof. We begin with some preliminary estimates. Since F is of class C^1 and $F'(x^*)$ is non-singular, there exists a neighborhood $B_\delta^M(x^*)$ and constants $c, C > 0$ such that $\|F'(x)\|_{M^{-1} \leftarrow M}$ and $\|F'(x)^{-1}\|_{M \leftarrow M^{-1}}$ hold for all $x \in B_\delta^M(x^*)$; compare [Lemma 5.25](#). The [mean value theorem 2.4](#) gives us

$$F(x^{(k+1)}) - F(x^*) = F'(x^* + \zeta^{(k)}(x^{(k+1)} - x^*)) (x^{(k+1)} - x^*)$$

²⁵briefly: $\|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \in o(\|x^{(k+1)} - x^{(k)}\|_M)$

²⁶briefly: $\|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \in o(\|x^{(k)} - x^*\|_M)$

²⁷briefly: $\|F(x^{(k)}) + F'(x^*)(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \in o(\|x^{(k+1)} - x^{(k)}\|_M)$

with some $\xi^{(k)} \in (0, 1)$. We thus conclude

$$c \|x^{(k+1)} - x^*\|_M \leq \|F(x^{(k+1)}) - F(x^*)\|_{M^{-1}} \leq C \|x^{(k+1)} - x^*\|_M. \quad (*)$$

for sufficiently large $k \in \mathbb{N}_0$.

Another application of the [mean value theorem 2.4](#) yields

$$\begin{aligned} & F(x^{(k+1)}) - F(x^{(k)}) \\ &= F'(x^{(k)} + \widehat{\xi}^{(k)}(x^{(k+1)} - x^{(k)}))(x^{(k+1)} - x^{(k)}) \quad \text{where } \widehat{\xi}^{(k)} \in (0, 1) \\ &= F'(x^{(k)})(x^{(k+1)} - x^{(k)}) + [F'(x^{(k)} + \widehat{\xi}^{(k)}(x^{(k+1)} - x^{(k)})) - F'(x^{(k)})](x^{(k+1)} - x^{(k)}) \end{aligned}$$

and thus

$$\begin{aligned} & \|F(x^{(k+1)}) - F(x^{(k)}) - F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ & \leq \|F'(x^{(k)} + \widehat{\xi}_k(x^{(k+1)} - x^{(k)})) - F'(x^{(k)})\|_{M^{-1} \leftarrow M} \|x^{(k+1)} - x^{(k)}\|_M. \end{aligned}$$

As in the proof of [Lemma 5.20](#) we can now exploit the uniform continuity of F' “near the $(x^{(k)})$ ”. This entails that, for any $\varepsilon > 0$, there exists an index $k_0 \in \mathbb{N}_0$ such that

$$\|F(x^{(k+1)}) - F(x^{(k)}) - F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \quad (**)$$

holds for all $k \geq k_0$.

[Statement \(i\)](#) \Rightarrow [Statement \(ii\)](#) and [Statement \(iii\)](#): The triangle inequality and the Q-superlinear convergence imply that, for sufficiently large k , we have

$$\|x^{(k)} - x^*\|_M \leq \|x^{(k)} - x^{(k+1)}\|_M + \|x^{(k+1)} - x^*\|_M \leq \|x^{(k)} - x^{(k+1)}\|_M + \frac{1}{2} \|x^{(k)} - x^*\|_M,$$

and thus

$$\|x^{(k)} - x^*\|_M \leq 2 \|x^{(k+1)} - x^{(k)}\|_M. \quad (***)$$

On the other hand, the triangle inequality and the Q-superlinear convergence also imply that

$$\|x^{(k+1)} - x^{(k)}\|_M \leq \|x^{(k+1)} - x^*\|_M + \|x^* - x^{(k)}\|_M \leq \frac{1}{2} \|x^{(k)} - x^*\|_M + \|x^* - x^{(k)}\|_M,$$

holds for sufficiently large k , whence

$$\|x^{(k+1)} - x^{(k)}\|_M \leq 2 \|x^{(k)} - x^*\|_M. \quad (****)$$

In other words, the quantities $\|x^{(k+1)} - x^{(k)}\|_M$ and $\|x^{(k)} - x^*\|_M$ “control each other” for k sufficiently large.

Let $\varepsilon > 0$ be arbitrary. We can estimate

$$\begin{aligned} & \|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ & \leq \|F(x^{(k+1)}) - F(x^{(k)}) - F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} + \|F(x^{(k+1)}) - F(x^*)\|_{M^{-1}} \\ & \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M + \|F(x^{(k+1)}) - F(x^*)\|_{M^{-1}} \quad \text{by } (**) \quad \underbrace{\hspace{1cm}}_{=0} \end{aligned}$$

for k sufficiently large. We need to address the second term in the previous inequality:

$$\begin{aligned} \|F(x^{(k+1)}) - F(x^*)\|_{M^{-1}} &\leq C \|x^{(k+1)} - x^*\|_M && \text{by } (*) \\ &\leq C \|x^{(k)} - x^*\|_M && \text{by the Q-superlinear convergence.} \end{aligned}$$

for k sufficiently large. Plugging this estimate into the previous inequality is [Statement \(ii\)](#).

Moreover, as we demonstrated in [\(****\)](#), $\|x^{(k)} - x^*\|_M$ and $\|x^{(k+1)} - x^{(k)}\|_M$ are different by at most a constant factor, we also have proved [Statement \(iii\)](#).

[Statement \(ii\)](#) or [Statement \(iii\)](#) \Rightarrow [Statement \(i\)](#): We estimate

$$\begin{aligned} &\|F(x^{(k+1)})\|_{M^{-1}} \\ &\leq \|F(x^{(k+1)}) - F(x^{(k)}) - F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} + \|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ &\leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M + \|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \quad \text{by } (**). \end{aligned}$$

By [Statement \(ii\)](#) or [Statement \(iii\)](#), the second term can be bounded by $\varepsilon \|x^{(k+1)} - x^{(k)}\|_M$ or $\varepsilon \|x^{(k)} - x^*\|_M$, respectively. In any case, we have

$$\|F(x^{(k+1)})\|_{M^{-1}} \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M + 2\varepsilon \|x^{(k+1)} - x^{(k)}\|_M = 3\varepsilon \|x^{(k+1)} - x^{(k)}\|_M$$

for sufficiently large k . In view of $x^{(k)} \rightarrow x^*$, we find $F(x^{(k+1)}) \rightarrow 0$ and thus $F(x^*) = 0$.

It remains to show the Q-superlinear convergence of $x^{(k)}$. For any $\varepsilon \in (0, c)$, we have

$$\begin{aligned} c \|x^{(k+1)} - x^*\|_M &\leq \|F(x^{(k+1)})\|_{M^{-1}} && \text{by } (*) \\ &\leq 3\varepsilon \|x^{(k+1)} - x^{(k)}\|_M \\ &\leq 6\varepsilon \|x^{(k+1)} - x^*\|_M && \text{by } (****), \end{aligned}$$

and thus

$$\|x^{(k+1)} - x^*\|_M \leq \frac{6\varepsilon}{c} \|x^{(k)} - x^*\|_M$$

for sufficiently large k . This shows the Q-superlinear convergence of $x^{(k)}$ to x^* w.r.t. the M -norm.

[Statement \(ii\)](#) \Leftrightarrow [Statement \(iv\)](#): The difference of the terms inside the norms on the left hand sides in [\(5.33a\)](#) and [\(5.33c\)](#) is $[F'(x^{(k)}) - F'(x^*)](x^{(k+1)} - x^{(k)})$. Its norm can be estimated as follows:

$$\begin{aligned} &\|[F'(x^{(k)}) - F'(x^*)](x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ &\leq \|F'(x^{(k)}) - F'(x^*)\|_{M^{-1} \leftarrow M} \|x^{(k+1)} - x^{(k)}\|_M \\ &\leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \quad \text{by the continuity of } F' \end{aligned}$$

for sufficiently large k . The triangle inequality, either in the form

$$\begin{aligned} &\|F(x^{(k)}) + F'(x^{(k)})(x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ &\leq \|F(x^{(k)}) + F'(x^*)(x^{(k+1)} - x^{(k)})\|_{M^{-1}} + \|[F'(x^{(k)}) - F'(x^*)](x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ &\leq \|F(x^{(k)}) + F'(x^*)(x^{(k+1)} - x^{(k)})\|_{M^{-1}} + \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \end{aligned}$$

or in the form

$$\begin{aligned} & \|F(x^{(k)}) + F'(x^*) (x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ & \leq \|F(x^{(k)}) + F'(x^{(k)}) (x^{(k+1)} - x^{(k)})\|_{M^{-1}} + \|[F'(x^{(k)}) - F'(x^*)] (x^{(k+1)} - x^{(k)})\|_{M^{-1}} \\ & \leq \|F(x^{(k)}) + F'(x^{(k)}) (x^{(k+1)} - x^{(k)})\|_{M^{-1}} + \varepsilon \|x^{(k+1)} - x^{(k)}\|_M, \end{aligned}$$

each for sufficiently large k , now shows the equivalence of [Statement \(ii\)](#) and [Statement \(iv\)](#). \square

We now apply this lemma to [Algorithm 5.34](#), where the sequence of iterates $x^{(k)}$ is generated via (5.32). The residual these iterates leave in the true Newton systems can be expressed as

$$\begin{aligned} & F(x^{(k)}) + F'(x^{(k)}) (x^{(k+1)} - x^{(k)}) \\ & = F(x^{(k)}) + F'(x^{(k)}) d^{(k)} \overbrace{=0} \\ & = F(x^{(k)}) + F'(x^{(k)}) d^{(k)} - F(x^{(k)}) - H^{(k)} d^{(k)} + \zeta^{(k)} \\ & = [F'(x^{(k)}) - H^{(k)}] d^{(k)} + \zeta^{(k)}. \end{aligned}$$

We thus obtain from [Lemma 5.36](#) the following corollary.

Corollary 5.37 (Characterization of fast local convergence). *Suppose that $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function and that $x^{(k)}$ is a sequence generated by (5.32) that converges to x^* with non-singular Jacobian $F'(x^*)$. Then the following are equivalent:*

(i) $x^{(k)}$ converges Q -superlinearly w.r.t. the M -norm, and we have $F(x^*) = 0$.

(ii) For any $\varepsilon > 0$ there exists an index $k_0 \in \mathbb{N}_0$ such that

$$\|[F'(x^{(k)}) - H^{(k)}] d^{(k)} + \zeta^{(k)}\|_{M^{-1}} \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \quad \text{for all } k \geq k_0. \quad (5.34a)$$

(iii) For any $\varepsilon > 0$ there exists an index $k_0 \in \mathbb{N}_0$ such that

$$\|[F'(x^{(k)}) - H^{(k)}] d^{(k)} + \zeta^{(k)}\|_{M^{-1}} \leq \varepsilon \|x^{(k)} - x^*\|_M \quad \text{for all } k \geq k_0. \quad (5.34b)$$

(iv) For any $\varepsilon > 0$ there exists an index $k_0 \in \mathbb{N}_0$ such that

$$\|[F'(x^*) - H^{(k)}] d^{(k)} + \zeta^{(k)}\|_{M^{-1}} \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M \quad \text{for all } k \geq k_0. \quad (5.34c)$$

This set of equivalent of conditions that **are necessary and sufficient** for the local Q -superlinear convergence are known as **Dennis-Moré conditions**, introduced in [Dennis, Moré, 1974](#). They exhibit that two requisites are sufficient to ensure fast convergence:

- (1) The residual in the linear system, $\|\zeta^{(k)}\|_{M^{-1}}$, goes to zero faster than $\|x^{(k+1)} - x^{(k)}\|_M$.
- (2) The difference between the Jacobian $F'(x^{(k)})$ and the model Jacobian $H^{(k)}$, evaluated in the direction of $d^{(k)}$, goes to zero faster than $\|x^{(k+1)} - x^{(k)}\|_M$. **Note:** It is not necessary for $H^{(k)}$ to approximate the Jacobian $F'(x^{(k)})$ in its entirety!

We will discuss in the following two classes of methods that are specializations of [Algorithm 5.34](#). The first class of methods are inexact Newton methods (§ 5.6), which use $H^{(k)} = F'(x^{(k)})$. The second class of methods are quasi-Newton algorithms (§ 5.7), which feature $\zeta^{(k)} = 0$.

§ 5.6 INEXACT NEWTON METHODS

Inexact Newton methods use the true Jacobian $H^{(k)} = F'(x^{(k)})$ in the linear systems (5.31), but they solve them only inexactly, leaving a residual $\zeta^{(k)}$:

$$F'(x^{(k)}) d^{(k)} = -F(x^{(k)}) + \zeta^{(k)} \quad (5.35)$$

We measure the norm of the residual in the linear system (5.35) relative to the norm of the outer residual $F(x^{(k)})$ associated with the current iterate $x^{(k)}$. We require

$$\|\zeta^{(k)}\|_{M^{-1}} = \|F'(x^{(k)}) d^{(k)} + F(x^{(k)})\|_{M^{-1}} \leq \eta^{(k)} \|F(x^{(k)})\|_{M^{-1}} \quad (5.36)$$

with some $\eta^{(k)} \in (0, 1)$. The sequence $(\eta^{(k)})$ is known as a **forcing sequence**.

Note that $F(x^{(k)})$ is the residual associated with the zero vector, and hence

$$\frac{\|\text{residual associated with } d^{(k)}\|_{M^{-1}}}{\|\text{residual associated with } 0\|_{M^{-1}}} = \frac{\|\zeta^{(k)}\|_{M^{-1}}}{\|F(x^{(k)})\|_{M^{-1}}} \leq \eta^{(k)}. \quad (5.37)$$

Thus we can interpret the forcing sequence as the relative reduction of the residual required in the linear system $F'(x^{(k)}) d^{(k)} = -F(x^{(k)})$, compared to a zero initial guess. It is evident that we should demand $\eta^{(k)} < 1$. Otherwise, $d^{(k)} = 0$ would constitute a sufficiently accurate solution.

We refer to [Algorithm 5.34](#) as an **inexact local Newton's method** in case $H^{(k)} = F'(x^{(k)})$. For completeness, we state the algorithm as

Algorithm 5.38 (local inexact Newton's method for $F(x) = 0$).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate F and F'

Input: spd Matrix M (oder Matrix-Vektor-Produkte mit M^{-1})

Input: routine to determine the forcing sequence $\eta^{(k)}$

Output: approximate zero of F

1: Set $k := 0$

2: **while** stopping criterion not met **do**

3: Determine a search direction $d^{(k)}$ by (inexactly) solving $F'(x^{(k)}) d^{(k)} = -F(x^{(k)})$ so that the residual $\zeta^{(k)} := F'(x^{(k)}) d^{(k)} + F(x^{(k)})$ satisfies the condition

$$\|\zeta^{(k)}\|_{M^{-1}} \leq \eta^{(k)} \|F(x^{(k)})\|_{M^{-1}} \quad (5.36)$$

4: Set $x^{(k+1)} := x^{(k)} + d^{(k)}$

5: Set $k := k + 1$

6: **end while**

7: **return** $x^{(k)}$

Note: With $\eta^{(k)} \equiv 0$, we obtain again the exact local Newton's method.

We can now specify a local convergence theorem for [Algorithm 5.38](#).

Theorem 5.39 (Convergence of [Algorithm 5.38](#); compare [Theorem 5.27](#)). *Suppose that $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a C^1 function and that $x^* \in \mathbb{R}^n$ is a point where $F(x^*) = 0$ and $F'(x^*)$ is non-singular. Suppose that $x^{(k)}$ is a sequence generated by [Algorithm 5.38](#), where the elements of the forcing sequence satisfy $\eta^{(k)} \leq \bar{\eta} < 1$ for all $k \in \mathbb{N}_0$. Then there exists a neighborhood $B_\delta^M(x^*)$ such that*

- (i) x^* is the unique zero of F in $B_\delta^M(x^*)$.
- (ii) For any initial guess $x^{(0)} \in B_\delta^M(x^*)$, the local inexact Newton's method is well-defined, and it generates a sequence $x^{(k)}$ which converges to x^* .
- (iii) $(x^{(k)})$ converges to x^* **Q-linearly** w.r.t. the M -norm.
- (iv) If, in addition, $\eta^{(k)} \searrow 0$ holds, then the convergence is **Q-superlinear**.
- (v) If F' is Lipschitz continuous in $B_\delta^M(x^*)$, and if, in addition to $\eta^{(k)} \searrow 0$, we even have $\eta^{(k)} \leq C \|F(x^{(k)})\|_{M^{-1}}$ with some constant $C > 0$, then this convergence is even **Q-quadratic**.

Proof. We only give a sketch of the proof. [Statement \(i\)](#) can be shown as [Theorem 5.27](#). A guide to proving [Statement \(ii\)](#) and [Statement \(iii\)](#) can be found in [Geiger, Kanzow, 1999](#), Satz 10.3. For [Statement \(iv\)](#), we use the characterization of Q-superlinear convergence by [Corollary 5.37](#). We have

$$\underbrace{\|(F'(x^{(k)}) - H^{(k)})d^{(k)} + \zeta^{(k)}\|_{M^{-1}}}_{=0} = \|\zeta^{(k)}\|_{M^{-1}} \leq \eta^{(k)} \|F(x^{(k)})\|_{M^{-1}} \quad \text{by (5.36).}$$

As in the proof of [Lemma 5.36](#), see (*), we have $\|F(x^{(k)})\|_{M^{-1}} \leq C \|x^{(k)} - x^*\|_M$ for sufficiently large indices k and thus

$$\|(F'(x^{(k)}) - H^{(k)})d^{(k)} + \zeta^{(k)}\|_{M^{-1}} \leq \eta^{(k)} C \|x^{(k)} - x^*\|_M.$$

Since $\eta^{(k)} \searrow 0$, we satisfy [\(5.34b\)](#).

[Statement \(v\)](#) follows similarly as in [Theorem 5.27](#). □

A possible rule for the choice of the forcing sequence $\eta^{(k)}$ that guarantees the local Q-superlinear convergence is

$$\eta^{(k)} := \min\{\bar{\eta}, \|F(x^{(k)})\|_{M^{-1}}^\theta\} \quad (5.38)$$

with some $\bar{\eta} < 1$ and $\theta \in (0, 1]$, for instance $\bar{\eta} = 1/2$ and $\theta = 0.5$.²⁸

²⁸More precisely, we even obtain the Q-superlinear convergence with rate $1 + \theta$ with this choice.

In the remainder of § 5.6 we consider a practical approach to the **inexact solution** of the Newton systems, while **simultaneously globalizing** the inexact local Newton's method (Algorithm 5.38). Since in this class we are discussing globalization for Newton-like methods only in the context of optimization (and not for general root-finding), we switch back to the optimization context now. That is, we have $F(x) = \nabla f(x)$ and $F'(x) = f''(x)$.

We need to take into account the following:

- (1) The Newton system $f''(x^{(k)}) d = -\nabla f(x^{(k)})$ is to be solved *iteratively*²⁹. In this way, we can take advantage of the fact that an inexact solution is sufficient and we can stop once the residual norm for the linear system falls below the threshold dictated by the forcing sequence; see (5.36). We refer to the inexact Newton direction as $d_N^{(k)}$.
- (2) The inexact Newton direction $d_N^{(k)}$ is required to be, at the very least, a descent direction for the objective f at the current outer iterate $x^{(k)}$.
- (3) As we did in the globalized exact Newton's method (Algorithm 5.30), we need to verify whether the inexact Newton direction $d_N^{(k)}$ offers sufficient descent. If not, then we fall back to taking a step in the steepest descent direction.

It turns out that we can reach the first and the second goal simultaneously by a clever use of the conjugate gradient method (Algorithm 4.17), applied to the symmetric linear system $A d = b$, where

$$A = f''(x^{(k)}) \quad \text{and} \quad b = -\nabla f(x^{(k)}).$$

As a stopping criterion, we employ the relative criterion (4.14a) with $\varepsilon_{\text{rel}} = \eta^{(k)}$, and the zero vector serves as initial guess. In case the CG algorithm finishes “without an incidence”, then – due to (5.37) – the solution returned is an inexact solution of the Newton system with sufficiently small residual norm in the sense of (5.36).

Remark 5.40 (inner and outer iterations). *In what follows we will sometimes use the terms inner iterations and outer iterations. The **outer iterations** of those of the outer optimization method, which is the inexact Newton's method in this subsection. The quantities used in the outer iterations are the iterates $x^{(k)}$, search directions $d^{(k)}$, step sizes $\alpha^{(k)}$, etc.*

*On the other hand, every search direction $d^{(k)}$ will now be found in an iterative way, which refer to as **inner iterations**. In order to help avoid confusion, we will denote the inner iteration index by ℓ . Also, the iterates of the inner solver for the linear system $A d = b$ will be termed $d^{(\ell)}$ instead of $x^{(\ell)}$. The search directions in the inner solver will be $p^{(\ell)}$ instead of $d^{(\ell)}$. The residuals in the inner solver will be $\zeta^{(\ell)}$ instead of $r^{(\ell)}$.*

What could be the incidences that might occur in the CG algorithm in the present context? On the one hand, we might reach the maximum number of iterations before reaching the relative tolerance. On

²⁹rather than using a direct solver such as Gaussian elimination

the other hand, the symmetric matrix A might not be positive definite. This means that the function

$$\phi(z) := \frac{1}{2} z^T A z - b^T z$$

has a least one direction $p \in \mathbb{R}^n$, $p \neq 0$, of non-positive curvature; i. e., $p^T A p \leq 0$ holds. A lack of positive definiteness does not mean that a search direction of non-positive curvature will actually be encountered during the inner iterations. On the one hand, the required tolerance may be reached beforehand. But even for exact solutions ($\varepsilon_{\text{rel}} = 0$), not all right hand sides b actually invoke directions of non-positive curvature.

In any case, if a direction $p^{(\ell)}$ with $\theta^{(\ell)} := (p^{(\ell)})^T A p^{(\ell)} \leq 0$ is encountered, a reaction is required since otherwise,

- in case $\theta^{(\ell)} = 0$, a division by zero would occur in [Line 8](#) of the CG algorithm ([Algorithm 4.17](#)),
- in case $\theta^{(\ell)} < 0$, the CG algorithm could be continued; however, we might lose the property that the iterates $d^{(\ell)}$ are descent directions for f at $x^{(k)}$. This can be confirmed by examples. As long as all search directions $p^{(\ell)}$ are directions of positive curvature ($\theta^{(\ell)} > 0$), the descent property remains intact; see [Lemma 5.42](#).

For the reasons above, it is customary to employ a variant of the CG method known as **truncated conjugate gradient method (truncated CG method)** as inner solver in a globalized inexact Newton method. Starting from a zero initial guess, iterate until either the relative stopping criterion ([4.14a](#)) is verified, or a search direction of non-positive curvature is encountered. In that case, the most recent iterate $d^{(\ell)}$ is returned as inexact solution.

For completeness, we state below the truncated CG algorithm. Notice that we chose the specific stopping criterion ([5.37](#)) instead of a general criterion.

Algorithm 5.41 (Truncated conjugate gradient method for symmetric systems $A d = b$ w.r.t. the M -inner product; compare [Algorithm 4.17](#)).

Input: right-hand side $b \in \mathbb{R}^n$

Input: symmetric matrix A (or matrix-vector products with A)

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Input: relative residual ε_{rel}

Output: approximate solution of $A d = b$

```

1: Set  $\ell := 0$ 
2: Set  $d^{(0)} := 0$  // zero initial guess
3: Set  $\zeta^{(0)} := -b$  // evaluate the initial residual
4: Set  $p^{(0)} := -M^{-1} \zeta^{(0)}$ 
5: Set  $\delta^{(0)} := -(\zeta^{(0)})^T p^{(0)}$  //  $\delta^{(0)} = \|\zeta^{(0)}\|_{M^{-1}}^2$ 
6: while  $\delta^{(\ell)} \geq \varepsilon_{\text{rel}}^2 \delta^{(0)}$  // check stopping criterion (5.37) do
7:   Set  $q^{(\ell)} := A p^{(\ell)}$ 
8:   Set  $\theta^{(\ell)} := (q^{(\ell)})^T p^{(\ell)}$ 
9:   if  $\theta^{(\ell)} > 0$  then
10:    Set  $\alpha^{(\ell)} := \delta^{(\ell)} / \theta^{(\ell)}$ 
```

```

11:      Set  $d^{(\ell+1)} := d^{(\ell)} + \alpha^{(\ell)} p^{(\ell)}$ 
12:      Set  $\zeta^{(\ell+1)} := \zeta^{(\ell)} + \alpha^{(\ell)} q^{(\ell)}$ 
13:      Set  $p^{(\ell+1)} := -M^{-1}\zeta^{(\ell+1)}$ 
14:      Set  $\delta^{(\ell+1)} := -(\zeta^{(\ell+1)})^\top p^{(\ell+1)}$   $\delta^{(\ell+1)} = \|\zeta^{(\ell+1)}\|_{M^{-1}}^2$ 
15:      Set  $\beta^{(\ell+1)} := \delta^{(\ell+1)} / \delta^{(\ell)}$ 
16:      Set  $p^{(\ell+1)} := p^{(\ell+1)} + \beta^{(\ell+1)} p^{(\ell)}$ 
17:      Set  $\ell := \ell + 1$ 
18:  else
19:      Abort the while loop
20:  end if
21: end while
22: return  $d^{(\ell)}$ 

```

It still remains to be proved that the approximate solution $d^{(\ell)}$ that the truncated CG method generates and that is to be used as inexact Newton direction $d_N^{(k)}$, is indeed a descent direction for the objective f at the current outer iterate $x^{(k)}$. This means that we need to show $f'(x^{(k)}) d^{(\ell)} < 0$ or equivalently, $b^\top d^{(\ell)} > 0$.

Lemma 5.42 (The truncated CG method generates descent directions). *Suppose that $b \neq 0$ and that $d^{(0)}, \dots, d^{(\ell)}$ have been generated by Algorithm 5.41 for some $\ell \geq 1$. Then the following holds.*

- (i) $b^\top M^{-1}\zeta^{(j)} = 0$ for $j = 1, \dots, \ell$.
- (ii) $b^\top p^{(j)} = \|\zeta^{(j)}\|_{M^{-1}}^2$ for $j = 0, \dots, \ell$.
- (iii) $b^\top d^{(\ell)} = \sum_{j=0}^{\ell-1} \alpha^{(j)} \|\zeta^{(j)}\|_{M^{-1}}^2$ is positive and strictly monotonically increasing in ℓ .

Proof. **Statement (i):** Since we use the zero vector as initial guess, we have $\zeta^{(0)} = A 0 - b = -b$ for the initial residual. Therefore,

$$b^\top M^{-1}\zeta^{(j)} = -(\zeta^{(0)})^\top M^{-1}\zeta^{(j)} = 0 \quad \text{for } j \geq 1$$

according to (4.28).

Statement (ii): The initial search direction is $p^{(0)} = -M^{-1}\zeta^{(0)}$, and hence we have

$$b^\top p^{(0)} = (\zeta^{(0)})^\top M^{-1}\zeta^{(0)} = \|\zeta^{(0)}\|_{M^{-1}}^2.$$

By induction, we find for $j \geq 0$:

$$\begin{aligned}
b^\top p^{(j+1)} &= b^\top (-M^{-1}\zeta^{(j+1)} + \beta^{(j+1)} p^{(j)}) \\
&= 0 + \beta^{(j+1)} b^\top p^{(j)} && \text{by Statement (i)} \\
&= \frac{\|\zeta^{(j+1)}\|_{M^{-1}}^2}{\|\zeta^{(j)}\|_{M^{-1}}^2} b^\top p^{(j)} && \text{by (4.24')} \\
&= \|\zeta^{(j+1)}\|_{M^{-1}}^2 && \text{by the induction hypothesis.}
\end{aligned}$$

Statement (iii): Since [Algorithm 5.41](#) generated the iterates $d^{(0)}, \dots, d^{(\ell)}$, the numbers $\theta^{(0)}, \dots, \theta^{(\ell-1)}$ are all strictly positive. Consequently, $\alpha^{(j)} = \delta^{(j)} / \theta^{(j)} > 0$ is also positive for $j = 0, \dots, \ell - 1$. We consider the expression

$$b^\top d^{(\ell)} = b^\top \sum_{j=0}^{\ell-1} \alpha^{(j)} p^{(j)} = \sum_{j=0}^{\ell-1} \alpha^{(j)} \|\zeta^{(j)}\|_{M^{-1}}^2$$

with the last equality due to [Statement \(ii\)](#). The residuals $\zeta^{(0)}, \dots, \zeta^{(\ell-1)}$ are all $\neq 0$, otherwise the stopping criterion in [Algorithm 5.41](#) would have been triggered. Therefore, the above expression is strictly increasing w.r.t. ℓ . \square

Remark 5.43 (on [Algorithm 5.41](#)).

- (i) The first search direction is $p^{(0)} = M^{-1}b$, which is equal to the steepest descent direction $-M^{-1}\nabla f(x^{(k)})$ in the optimization context. When $p^{(0)}$ is a direction of positive curvature (if $\theta^{(0)} > 0$), then $d^{(1)}$ is the same as though we had applied the steepest descent method with Cauchy step size ([Algorithm 4.6](#)).
- (ii) By contrast, when $p^{(0)}$ is a direction of non-positive curvature, [Algorithm 5.41](#) stops and returns $d^{(0)} = 0$. This is, of course, not a useful descent direction for the outer, inexact Newton method, as will be detected by a quality test for the inexact Newton direction, and a fallback to a gradient step will be the consequence.
- (iii) The strictly increasing monotonicity of $b^\top d^{(\ell)} = -f'(x^{(k)}) d^{(\ell)}$ w.r.t. the iteration counter ℓ means that the descent properties of the iterates $d^{(\ell)}$ progressively improve, as long as the search directions $p^{(\ell)}$ remain directions of positive curvature for A . Therefore, it is reasonable to continue performing CG iterations until either the desired tolerance is reached, or a direction of non-positive curvature is encountered. This is the strategy [Algorithm 5.41](#) is following.

As we already mentioned, the globalization of the inexact Newton method can be done along the same lines as in [Algorithm 5.30](#). This leads to the following algorithm.

Algorithm 5.44 (Globalized inexact Newton method for (UP); compare [Algorithm 5.30](#)).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Input: routine to evaluate f'' (or matrix-vector products with f'')

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Input: routine to determine the forcing sequence $\eta^{(k)}$

Input: globalization parameters $\eta \in (0, 1)$, $\rho > 0$ and exponent $p > 0$

Input: Armijo parameter $\sigma \in (0, 1/2)$ // to be passed through to the Armijo backtracking line search

Input: backtracking parameter $\beta \in (0, 1)$ // to be passed through to the Armijo backtracking line search

Output: approximately stationary point of (UP)

1: Set $k := 0$

2: Set $f^{(0)} := f(x^{(0)})$

// evaluate the initial objective value

3: Set $r^{(0)} := f'(x^{(0)})^\top = \nabla f(x^{(0)})$

// evaluate the initial residual

4: Set $d_G^{(0)} := -M^{-1}r^{(0)}$

// evaluate the negative M -gradient

```

5: Set  $\delta^{(0)} := -(r^{(0)})^\top d_G^{(0)}$   $\delta^{(0)} = \|\nabla_M f(x^{(0)})\|_M^2 = \|d_G^{(0)}\|_M^2$ 
6: while stopping criterion not met do
7:   Determine the inexact Newton direction  $d_N^{(k)}$  using Algorithm 5.41 with  $A = f''(x^{(k)})$ ,  $b = -r^{(k)}$ ,
   preconditioner  $M$  and relative residual  $\varepsilon_{\text{rel}} = \eta^{(k)}$ 
8:   Evaluate the generalized angle condition for the Newton direction

$$f'(x^{(k)}) d_N^{(k)} \leq -\min\{\eta, \rho \|d_G^{(k)}\|_M^p\} \|d_G^{(k)}\|_M \|d_N^{(k)}\|_M \quad (5.27)$$

9:   if true then
10:     Set  $d^{(k)} := d_N^{(k)}$   $\text{// use the inexact Newton direction}$ 
11:   else
12:     Set  $d^{(k)} := d_G^{(k)}$   $\text{// use the steepest descent direction as fallback}$ 
13:   end if
14:   Determine a step size  $\alpha^{(k)} > 0$  from an Armijo backtracking line search procedure (Algorithm 5.11),
   applied to  $\varphi(\alpha) := f(x^{(k)} + \alpha d^{(k)})$ , with initial trial step size  $\alpha^{(k,0)} = 1$ , Armijo parameter  $\sigma$  and
   backtracking parameter  $\beta$   $\text{// } \varphi(0) = f^{(k)} \text{ and } \varphi'(0) = (r^{(k)})^\top d^{(k)} = -\delta^{(k)} \text{ in case of } d^{(k)} = d_G^{(k)}, \text{ or}$ 
 $\varphi'(0) = f'(x^{(k)}) d_N^{(k)} \text{ in case of } d^{(k)} = d_N^{(k)}, \text{ are already known}$ 
15:   Set  $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$ 
16:   Set  $f^{(k+1)} := f(x^{(k+1)})$   $\text{// can be returned by the Armijo backtracking line search routine}$ 
17:   Set  $r^{(k+1)} := f'(x^{(k+1)})^\top = \nabla f(x^{(k+1)})$ 
18:   Set  $d_G^{(k+1)} := -M^{-1}r^{(k+1)}$   $\text{// evaluate the negative } M\text{-gradient}$ 
19:   Set  $\delta^{(k+1)} := -(r^{(k+1)})^\top d_G^{(k+1)}$   $\delta^{(k+1)} = \|\nabla_M f(x^{(k+1)})\|_M^2 = \|d_G^{(k+1)}\|_M^2$ 
20:   Set  $k := k + 1$ 
21: end while
22: return  $x^{(k)}$ 

```

Remark 5.45 (on [Algorithm 5.44](#)).

- (i) See [Remark 5.31](#) on choosing the globalization parameters ρ and p .
- (ii) The quantity $\|d_N^{(k)}\|_M$ required to evaluate the generalized angle condition (5.27) can be returned at negligible additional cost by the truncated CG algorithm ([Algorithm 5.41](#)), as described in (4.33)–(4.34).

The global convergence of [Algorithm 5.44](#) can be verified very similarly as in [Theorem 5.32](#). In fact, ?? in the proof (admissibility of search directions) remains exactly the same since the generalized angle condition and the fallback to steepest descent directions remains the same as in [Algorithm 5.30](#). In ?? (admissibility of step sizes), we need to take into account the fact that the inexact Newton direction satisfies the Newton system only with a residual. We end up replacing the estimate (5.28) by

$$\|d^{(k)}\|_M \geq \min\left\{\frac{1-\eta^{(k)}}{C}, 1\right\} \|\nabla_M f(x^{(k)})\|_M \geq \min\left\{\frac{1-\eta^{(k)}}{C}, 1\right\} \frac{-f'(x^{(k)}) d^{(k)}}{\|d^{(k)}\|_M} \quad (5.39)$$

for all $k \in K$, and we have to modify the function ψ accordingly. (**Quiz 5.7:** Can you fill in the details?)

The transition to fast local convergence can be shown similarly as in [Theorem 5.33](#). We can verify again that

$$d^{(k)} = d_N^{(k)} \quad \text{and} \quad \alpha^{(k)} = 1 \quad (5.29)$$

holds for sufficiently large indices k . Consequently, the convergence mode (Q-linear, Q-superlinear or even Q-quadratic) follows depending on the choice of forcing sequence, using [Theorem 5.39](#); see also [Geiger, Kanzow, 1999](#), Satz 10.8.

The combination of the inexact Newton method as outer algorithm with the truncated CG algorithm as inner solver is often referred to as **truncated Newton CG method**. Since we do not necessarily need to set up the full Hessian matrix $f''(x^{(k)})$, but matrix-vector products with $f''(x^{(k)})$ are sufficient, one also speaks of a **Hessian-free optimization**. Matrix-vector products with $f''(x^{(k)})$ can be realized, e. g., using algorithmic differentiation techniques ([Chapter 4](#)).

End of Week 5

§ 5.7 QUASI-NEWTON METHODS

In contrast to inexact Newton methods (§ 5.6), **quasi-Newton methods** make use of the freedom Newton-like methods offer in a different way. We discuss quasi-Newton methods only in the context of optimization. A quasi-Newton method determines symmetric (and often positive definite) approximations $H^{(k)}$ of the Hessians $f''(x^{(k)})$ but then solves the systems

$$H^{(k)} d^{(k)} = -\nabla f(x^{(k)}) \quad (5.40)$$

exactly before taking a step in the direction $d^{(k)}$. Quasi-Newton methods are also known as **variable metric methods** since, in contrast to gradient methods which maintain $H^{(k)} \equiv M$ constant, the model Hessian $H^{(k)}$ changes from iteration to iteration.

The model Hessian $H^{(k+1)}$ is constructed based on information gained in the k -th step. A consistent requirement in all quasi-Newton methods is the so-called **secant condition** or **quasi-Newton condition**,

$$H^{(k+1)}(x^{(k+1)} - x^{(k)}) = \nabla f(x^{(k+1)}) - \nabla f(x^{(k)}). \quad (5.41)$$

This condition can be motivated in several ways:

- (1) It follows from the fundamental theorem of calculus³⁰ that

$$\nabla f(x + d) = \nabla f(x) + f''(x + d) d + \int_0^1 [f''(x + t d) - f''(x + d)] d \, dt \quad (5.42)$$

holds for all $x, d \in \mathbb{R}^n$. For the integral term, we have the following estimate, which uses the C^2 property of f : for any $\varepsilon > 0$, there exists $\delta > 0$ such that

$$\left\| \int_0^1 [f''(x + t d) - f''(x + d)] d \, dt \right\|_{M^{-1}} \leq \varepsilon \|d\|_M$$

³⁰The function $t \mapsto \nabla f(x + t d)$ is the integral of its derivative $t \mapsto f''(x + t d) d$, and thus $\int_0^1 f''(x + t d) d \, dt = \nabla f(x + t d)|_0^1 = \nabla f(x + d) - \nabla f(x)$

holds for all $\|d\|_M \leq \delta$.³¹

Omitting this integral term from (5.42), plugging in $x^{(k)}$ for x and $x^{(k+1)} - x^{(k)}$ for d , and replacing the true Hessian $f''(x + d)$ by its approximation $H^{(k+1)}$, we obtain

$$\nabla f(x^{(k+1)}) = \nabla f(x^{(k)}) + H^{(k+1)}(x^{(k+1)} - x^{(k)}),$$

which is the secant condition (5.41). Hence the secant condition approximately mimics the property (5.42) of the true Hessian.

(2) Let us consider the two quadratic models³² at the consecutive iterates $x^{(k)}$ and $x^{(k+1)}$,

$$m^{(k)}(x) = f(x^{(k)}) + f'(x^{(k)})(x - x^{(k)}) + \frac{1}{2}(x - x^{(k)})^\top H^{(k)}(x - x^{(k)}), \quad (5.43a)$$

$$m^{(k+1)}(x) = f(x^{(k+1)}) + f'(x^{(k+1)})(x - x^{(k+1)}) + \frac{1}{2}(x - x^{(k+1)})^\top H^{(k+1)}(x - x^{(k+1)}). \quad (5.43b)$$

By construction, the derivative of the old model $m^{(k)}$ agrees with the derivative of f at $x^{(k)}$. Also, the derivative of the new model $m^{(k+1)}$ agrees with the derivative of f at $x^{(k+1)}$. We require now, in addition, that the *derivative of the new model* agrees with the derivative of f also *at the old iterate* $x^{(k)}$, i. e.,

$$\begin{aligned} & (m^{(k+1)})'(x^{(k)}) = f'(x^{(k)}) \\ \Leftrightarrow & \nabla m^{(k+1)}(x^{(k)}) = \nabla f(x^{(k)}) \\ \Leftrightarrow & \nabla f(x^{(k+1)}) + H^{(k+1)}(x^{(k)} - x^{(k+1)}) = \nabla f(x^{(k)}), \quad \text{since } H^{(k+1)} \text{ is symmetric} \\ \Leftrightarrow & \text{secant condition (5.41).} \end{aligned}$$

Using the Dennis-Moré conditions (Corollary 5.37) for Newton-like methods, we can now characterize the fast (Q-superlinear) local convergence (without line search) of quasi-Newton methods.

Theorem 5.46 (Fast local convergence of quasi-Newton methods). *Suppose that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is a C^2 function. Suppose that the sequence $x^{(k)}$ is generated using the Newton-like method Algorithm 5.34 with model Hessians $H^{(k)}$ which are symmetric and satisfy the secant condition (5.41), and with zero residuals $\zeta^{(k)} = 0$. Suppose that $x^{(k)}$ converges to x^* , where $f''(x^*)$ is non-singular. Finally, suppose that for any $\varepsilon > 0$, there exists $\delta > 0$ such that*

$$\|(H^{(k+1)} - H^{(k)})d^{(k)}\|_{M^{-1}} \leq \varepsilon \|d^{(k)}\|_M \quad (5.44)$$

holds for all $\|d^{(k)}\|_M \leq \delta$.³³ Then the conditions of Corollary 5.37 hold, and therefore $x^{(k)}$ converges to x^ Q-superlinearly w.r.t. the M -norm, and $f'(x^*) = 0$ holds.*

³¹We could likewise say that the left-hand side belongs to $o(\|d\|_M)$.

³²In contrast to (5.2), we write the model here in terms of x , not in terms of the direction d , which is notationally more convenient. That is, we write $m^{(k)}(x)$ rather than $q^{(k)}(d)$.

³³In other words, $\|(H^{(k+1)} - H^{(k)})d^{(k)}\|_{M^{-1}} \in o(\|d^{(k)}\|_M)$

Proof. We can estimate

$$\begin{aligned} & \| (f''(x^{(k)}) - H^{(k)}) d^{(k)} \|_{M^{-1}} \\ & \leq \| (f''(x^{(k)}) - H^{(k+1)}) d^{(k)} \|_{M^{-1}} + \| (H^{(k+1)} - H^{(k)}) d^{(k)} \|_{M^{-1}} \quad \text{by the triangle inequality.} \end{aligned}$$

By assumption, the second term is bounded by $\varepsilon \|d^{(k)}\|_M$, provided that $\|d^{(k)}\|_M \leq \delta$:

$$\leq \|f''(x^{(k)}) d^{(k)} - \nabla f(x^{(k+1)}) + \nabla f(x^{(k)})\|_{M^{-1}} + \varepsilon \|d^{(k)}\|_M \quad \text{by the secant condition.}$$

Using the uniform continuity of f'' “near the $(x^{(k)})$ ” (as in the proof of [Lemma 5.13](#)), we can bound the first term by $\varepsilon \|x^{(k+1)} - x^{(k)}\|_M$, provided that $\|x^{(k+1)} - x^{(k)}\|_M$ is sufficiently small:

$$\begin{aligned} & \leq \varepsilon \|x^{(k+1)} - x^{(k)}\|_M + \varepsilon \|d^{(k)}\|_M \\ & = 2\varepsilon \|x^{(k+1)} - x^{(k)}\|_M. \end{aligned}$$

We have shown that condition (5.34a) of [Corollary 5.37](#) holds, which implies the Q-superlinear convergence and the stationarity of x^* . \square

In view of

$$\|(H^{(k+1)} - H^{(k)}) d^{(k)}\|_{M^{-1}} \leq \|H^{(k+1)} - H^{(k)}\|_{M^{-1} \leftarrow M} \|d^{(k)}\|_M,$$

the convergence $H^{(k+1)} - H^{(k)} \rightarrow 0$ is sufficient to ensure the prerequisite (5.44) of [Theorem 5.46](#).

Let us now discuss how to construct quasi-Newton matrices $H^{(k)}$ in practice. From now on, we also include a step size $\alpha^{(k)} > 0$ in the update of the iterates

$$x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}.$$

To simplify notation, we introduce

$$s^{(k)} := x^{(k+1)} - x^{(k)} = \alpha^{(k)} d^{(k)} \quad \text{and} \quad y^{(k)} := \nabla f(x^{(k+1)}) - \nabla f(x^{(k)}). \quad (5.45)$$

One important class of quasi-Newton methods constructs $H^{(k+1)}$ as a function of the previous matrix $H^{(k)}$ and the two vectors $s^{(k)}$ and $y^{(k)}$:

$$H^{(k+1)} := \Phi(H^{(k)}, s^{(k)}, y^{(k)}). \quad (5.46)$$

Due to the dependence of $H^{(k+1)}$ on $H^{(k)}$, we also speak of a **quasi-Newton update formula**.

For reference purposes, we state a generic line-search quasi-Newton method in [Algorithm 5.47](#).

Algorithm 5.47 (Generic globalized quasi-Newton method for (UP)).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Input: initial symmetric model Hessian $H^{(0)} \in \mathbb{R}^{n \times n}$ (possibly s. p. d.)

Input: routine that implements the quasi-Newton update Φ

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Output: approximately stationary point of (UP)

```

1: Set  $k := 0$ 
2: Set  $f^{(0)} := f(x^{(0)})$  // evaluate the initial objective value
3: Set  $r^{(0)} := f'(x^{(0)})^\top = \nabla f(x^{(0)})$  // evaluate the initial residual
4: Set  $d_G^{(0)} := -M^{-1}r^{(0)}$  // evaluate the negative M-gradient
5: Set  $\delta^{(0)} := -(r^{(0)})^\top d_G^{(0)}$  //  $\delta^{(0)} = \|\nabla_M f(x^{(0)})\|_M^2 = \|d_G^{(0)}\|_M^2$ 
6: while stopping criterion not met do
7:   Determine the quasi-Newton direction  $d^{(k)}$  by solving

$$H^{(k)}d^{(k)} = -r^{(k)} \quad (5.40)$$

8:   Determine a step size  $\alpha^{(k)} > 0$  from a line search procedure with preferred step size  $\alpha^{(k)} = 1$ 
9:   Set  $s^{(k)} := \alpha^{(k)}d^{(k)}$ 
10:  Set  $x^{(k+1)} := x^{(k)} + s^{(k)}$ 
11:  Set  $f^{(k+1)} := f(x^{(k+1)})$ 
12:  Set  $r^{(k+1)} := f'(x^{(k+1)})^\top = \nabla f(x^{(k+1)})$ 
13:  Set  $d_G^{(k+1)} := -M^{-1}r^{(k+1)}$  // evaluate the negative M-gradient
14:  Set  $\delta^{(k+1)} := -(r^{(k+1)})^\top d_G^{(k+1)}$  //  $\delta^{(k+1)} = \|\nabla_M f(x^{(k+1)})\|_M^2 = \|d_G^{(k+1)}\|_M^2$ 
15:  Set  $y^{(k)} := r^{(k+1)} - r^{(k)}$ 
16:  Determine the quasi-Newton matrix  $H^{(k+1)} := \Phi(H^{(k)}, s^{(k)}, y^{(k)})$ 
17:  Set  $k := k + 1$ 
18: end while
19: return  $x^{(k)}$ 

```

We recall the following desirable properties:

- (1) $H^{(k+1)}$ must be symmetric (provided that $H^{(k)}$ is symmetric).
- (2) $H^{(k+1)}$ must satisfy the secant condition (5.41), now written in the form

$$H^{(k+1)}s^{(k)} = y^{(k)}. \quad (5.47)$$

- (3) $H^{(k+1)}$ should be close to $H^{(k)}$ in the sense that $\|(H^{(k+1)} - H^{(k)})s^{(k)}\|_{M^{-1}} \in o(\|s^{(k)}\|_M)$ in order to satisfy the condition (5.44) for fast local convergence.
- (4) Ideally, the matrix $H^{(k+1)}$ should be positive definite (provided that $H^{(k)}$ is positive definite).

Notice that condition (4) guarantees that $d^{(k)}$, and thus $s^{(k)} = \alpha^{(k)}d^{(k)}$, is a descent direction.

A necessary condition for the positive definiteness of $H^{(k+1)}$ is obtained by multiplying the secant condition (5.41) by $s^{(k)}$:

$$0 < \underbrace{(s^{(k)})^\top H^{(k+1)} s^{(k)}}_{\text{evaluation of the bilinear form } H^{(k+1)} \text{ in the particular direction } s^{(k)}} = (y^{(k)})^\top s^{(k)} = (f'(x^{(k+1)}) - f'(x^{(k)}))(x^{(k+1)} - x^{(k)}). \quad (5.48)$$

For strictly convex functions, (5.48) is always satisfied in view of Theorem 2.9; see (2.26). Otherwise, we need a line search procedure to guarantee (5.48). The Wolfe-Powell line search lends itself for this purpose.

Lemma 5.48 (Wolfe-Powell line search ensures (5.48)). *Suppose that $d^{(k)}$ is a descent direction for f at $x^{(k)}$. If $\alpha^{(k)} > 0$ satisfies the curvature condition (5.17) for some $\tau < 1$, then the necessary condition (5.48) for positive definiteness of $H^{(k+1)}$ is satisfied.*

Proof. We can estimate

$$\begin{aligned} f'(x^{(k+1)}) d^{(k)} &\geq \tau f'(x^{(k)}) d^{(k)} && \text{by the curvature condition (5.17)} \\ &> f'(x^{(k)}) d^{(k)} && \text{since } d^{(k)} \text{ is a descent condition.} \end{aligned}$$

This can be rewritten as

$$(y^{(k)})^\top d^{(k)} > 0,$$

and since $s^{(k)} = \alpha^{(k)} d^{(k)}$ holds with positive step size $\alpha^{(k)}$, (5.48) follows. \square

There are infinitely many possibilities (in case $n > 1$) to satisfy the secant condition (5.47). (**Quiz 5.8:** Why?) We are now describing some of the most prominent quasi-Newton update formulas of the form

$$H^{(k+1)} := \Phi(H^{(k)}, s^{(k)}, y^{(k)}). \quad (5.46)$$

- **SR1 (Symmetric rank-1)** update:

There is only one symmetric rank-1 update formula that satisfies the secant condition (Nocedal, Wright, 2006, Chapter 6.2), and it is given by

$$\Phi_{\text{SR1}}(H, s, y) = H + \frac{(y - Hs)(y - Hs)^\top}{(y - Hs)^\top s}, \quad (5.49)$$

which requires that $H^{(k)} s^{(k)} \neq y^{(k)}$ holds throughout the iterations. That, however, is problematic. Suppose that we have taken a full step ($\alpha^{(k)} = 1$), i. e., $s^{(k)} = d^{(k)}$ holds. Suppose, moreover, that the step size $\alpha^{(k)} = 1$ gave us an almost stationary point of the line search function φ . Then

$$\begin{aligned} (y^{(k)} - H^{(k)} s^{(k)})^\top s^{(k)} &= (y^{(k)} - H^{(k)} d^{(k)})^\top d^{(k)} && \text{due to } s^{(k)} = d^{(k)} \\ &= (\nabla f(x^{(k+1)}) - \nabla f(x^{(k)}) - H^{(k)} d^{(k)})^\top d^{(k)} && \text{since } y^{(k)} = \nabla f(x^{(k+1)}) - \nabla f(x^{(k)}) \\ &= f'(x^{(k+1)}) d^{(k)} && \text{due to the quasi-Newton system (5.40)} \\ &= \varphi'(\alpha^{(k)}), \end{aligned}$$

which is almost zero.

Moreover, the positive definiteness of $H_{\text{SR1}}^{(k+1)}$ cannot be guaranteed, even if $H^{(k)}$ was positive definite, since the denominator in (5.49) may be negative. (Still, the SR1 has its purpose, in particular in the context of trust-region methods.)

- **PSB (Powell-symmetric-Broyden)** update:

Condition (3) from our list of desirable properties suggests to keep $H^{(k+1)}$ close to $H^{(k)}$. To this

end, we consider the auxiliary problem

$$\begin{aligned} & \text{Minimize} \quad \frac{1}{2} \|H^{(k+1)} - H^{(k)}\|_F^2, \quad \text{where } H^{(k+1)} \in \mathbb{R}_{\text{sym}}^{n \times n} \\ & \text{subject to} \quad \text{the secant condition (5.47).} \end{aligned} \quad (5.50)$$

Here $\|\cdot\|_F$ is the Frobenius norm, see (2.7). Problem (5.50) can be shown to have a unique solution³⁴, which is given in terms of the update formula

$$\Phi_{\text{PSB}}(H, s, y) = H + \frac{(y - Hs)s^\top + s(y - Hs)^\top}{s^\top s} - (y - Hs)^\top s \frac{s s^\top}{(s^\top s)^2} \quad (5.51)$$

This formula is said to be a **rank-2 update** since the rank of $H^{(k+1)} - H^{(k)}$ is at most 2. To see this, consider that Φ_{PSB} is of the form

$$\begin{aligned} \Phi_{\text{PSB}}(H, s, y) &= H + v s^\top + s v^\top + \gamma s s^\top \quad \text{with } v = (y - Hs)/\|s\|^2 \text{ and } \gamma = \frac{v^\top s}{\|s\|^2} \\ &= H + \underbrace{\gamma (s - \gamma^{-1}v)(s - \gamma^{-1}v)^\top}_{\text{symmetric, rank 1}} - \underbrace{\gamma^{-1}v v^\top}_{\text{symmetric, rank 1}}. \end{aligned}$$

Like SR₁, the PSB update formula also cannot guarantee the positive definiteness.

- **DFP (Davidon-Fletcher-Powell) update:**

The DFP update considers an auxiliary problem

$$\begin{aligned} & \text{Minimize} \quad \frac{1}{2} \|W^{-\top}(H^{(k+1)} - H^{(k)})W^{-1}\|_F^2, \quad \text{where } H^{(k+1)} \in \mathbb{R}_{\text{sym}}^{n \times n} \\ & \text{subject to} \quad \text{the secant condition (5.47),} \end{aligned}$$

where W is any non-singular matrix with the property $W^\top W s^{(k)} = y^{(k)}$. Using (2.6) and the property $\text{trace}(ABC) = \text{trace}(BCA)$ for products of matrices, and setting $M := W^\top W$ (which is s. p. d.), we can rewrite this problem as

$$\begin{aligned} & \text{Minimize} \quad \frac{1}{2} \text{trace}(M^{-1}(H^{(k+1)} - H^{(k)})M^{-1}(H^{(k+1)} - H^{(k)})), \quad \text{where } H^{(k+1)} \in \mathbb{R}_{\text{sym}}^{n \times n} \\ & \text{subject to} \quad \text{the secant condition (5.47)} \end{aligned} \quad (5.52)$$

with data $M s^{(k)} = y^{(k)}$.³⁵

It can be shown that the unique solution of problem (5.52) is independent of M and it is given by

$$\begin{aligned} \Phi_{\text{DFP}}(H, s, y) &= (\text{Id} - \rho y s^\top) H (\text{Id} - \rho s y^\top) + \rho y y^\top \\ &= H + \rho (y - Hs) y^\top + \rho y (y - Hs)^\top - \rho^2 (y - Hs)^\top s y y^\top, \end{aligned} \quad (5.53)$$

where $\rho = 1/(y^\top s)$. This update formula can be seen to also be of rank 2. This time, positive definiteness can be guaranteed; see Lemma 5.49.

³⁴see for instance Ulbrich, Ulbrich, 2012, p.76

³⁵The average Hessian $\int_0^1 f''(x^{(k)} + t s^{(k)}) dt$ is one possible matrix M , provided it is positive definite.

- **BFGS (Broyden-Fletcher-Goldfarb-Shanno)** update:

The BFGS formula starts from the optimization problem

$$\begin{aligned} & \text{Minimize} \quad \frac{1}{2} \|W[(H^{(k+1)})^{-1} - (H^{(k)})^{-1}] W^T\|_F^2, \quad H^{(k+1)} \in \mathbb{R}_{\text{sym}}^{n \times n} \\ & \text{subject to} \quad \text{the secant condition (5.47),} \end{aligned}$$

where W is again any non-singular matrix with the property $W^T W s^{(k)} = y^{(k)}$. Similarly as in (5.52), we can rewrite this problem as

$$\begin{aligned} & \text{Minimize} \quad \frac{1}{2} \text{trace}(M[(H^{(k+1)})^{-1} - (H^{(k)})^{-1}] M[(H^{(k+1)})^{-1} - (H^{(k)})^{-1}]), \quad H^{(k+1)} \in \mathbb{R}_{\text{sym}}^{n \times n} \\ & \text{subject to} \quad \text{the secant condition (5.47)} \end{aligned} \tag{5.54}$$

with data $M s^{(k)} = y^{(k)}$.

The solution of this problem — once again independent of W — results in the rank-2 update formula

$$\Phi_{\text{BFGS}}(H, s, y) = H - \frac{H s s^T H}{s^T H s} + \rho y y^T \tag{5.55}$$

where $\rho = 1/(y^T s)$. Also here, Lemma 5.49 will ensure the positive definiteness.

- **Broyden class** update:

The update formulas of the Broyden class are the affine combinations of the DFP and BFGS formulas. For any parameter $\lambda \in \mathbb{R}$, we obtain

$$\Phi_{\text{Broyden}}^\lambda(H, s, y) = (1 - \lambda) \Phi_{\text{BFGS}}(H, s, y) + \lambda \Phi_{\text{DFP}}(H, s, y). \tag{5.56}$$

The formulas obtained by restricting $\lambda \in [0, 1]$ are known as the **convex Broyden class**.

In (5.48) we had identified $y^T s > 0$ as a necessary condition for any quasi-Newton update formula satisfying the secant condition to be positive definite. Indeed, this condition is already sufficient in case of the DFP and BFGS updates. Consequently, the positive definiteness can be ensured using a Wolfe-Powell line search as we proved in Lemma 5.48.

Lemma 5.49 (Positive definiteness of the DFP and BFGS updates). *Suppose that H is symmetric and positive definite and that $y^T s > 0$ holds. Then $H_{\text{BFGS}}^+ := \Phi_{\text{BFGS}}(H, s, y)$ and $H_{\text{DFP}}^+ := \Phi_{\text{DFP}}(H, s, y)$ are symmetric and positive definite as well.*

Note: One can show this result even for all members of the non-negative Broyden class ($\lambda \geq 0$); see Ulbrich, Ulbrich, 2012, Satz 13.4.

Proof. The symmetry of H_{BFGS}^+ and H_{DFP}^+ are obvious. For any $v \in \mathbb{R}^n$, $v \neq 0$, we have

$$v^T H_{\text{DFP}}^+ v = (v^T - \rho (v^T y) s^T) H (v - \rho s (v^T y)) + \rho (v^T y)^2 \geq 0.$$

Equality in this inequality can hold only if both summands are zero. The first summand is zero precisely when v is a certain multiple of s , but in that case the second summand will be strictly positive due to $\rho = 1/(y^\top s) > 0$.

As for BFGS, we have

$$v^\top H_{\text{BFGS}}^+ v = v^\top H v - \frac{(s^\top H v)^2}{s^\top H s} + \rho (y^\top v)^2$$

By the Cauchy-Schwarz inequality w.r.t. the H -inner product, we can estimate this as

$$\begin{aligned} v^\top H_{\text{BFGS}}^+ v &\geq v^\top H v - \frac{(s^\top H s)(v^\top H v)}{s^\top H s} + \frac{(y^\top v)^2}{y^\top s} \\ &= \frac{(y^\top v)^2}{y^\top s} \\ &\geq 0. \end{aligned}$$

If this expression were equal to zero, then both inequalities would need to be equalities. In the first inequality, this implies that v is a (non-zero) multiple of s . But then the second inequality is strict since $y^\top s > 0$ holds. \square

While quasi-Newton methods avoid the evaluation of second-order derivatives of the objective f , we still need to solve a linear system (5.40) in every iteration. This brings up the question whether we could perhaps work with the *inverse matrix*³⁶ $B^{(k)} = (H^{(k)})^{-1}$ and avoid the solution of linear systems altogether, by evaluating

$$d^{(k)} = -B^{(k)} \nabla f(x^{(k)}) \quad \text{instead of solving} \quad H^{(k)} d^{(k)} = -\nabla f(x^{(k)}). \quad (5.57)$$

This is indeed possible, and we can find update formulas for the inverse matrices. The fact that common update formulas for $H^{(k)}$ are of low rank can be exploited, and it leads to low-rank update formulas for $B^{(k)}$. This is a consequence of the following key result, which has applications far beyond quasi-Newton methods.

Lemma 5.50 (Sherman-Morrison-Woodbury formula). *Suppose that $A \in \mathbb{R}^{n \times n}$ and $C \in \mathbb{R}^{r \times r}$ are non-singular matrices and that $U \in \mathbb{R}^{n \times r}$, $V \in \mathbb{R}^{r \times n}$ are arbitrary. Then $A + U C V$ is non-singular if and only if $C^{-1} + V A^{-1} U$ is non-singular. In this case,*

$$(A + U C V)^{-1} = A^{-1} - A^{-1} U (C^{-1} + V A^{-1} U)^{-1} V A^{-1}. \quad (5.58)$$

The significance of this lemma is the following. Typically we have $r \ll n$. Knowing the inverse A^{-1} , we can evaluate the inverse of the perturbed matrix $A + U C V$ with little effort, since the matrix $C^{-1} + V A^{-1} U$ on the right hand side, which is to be inverted, is only of size $r \times r$. In particular, the [Sherman-Morrison-Woodbury lemma 5.50](#) states that the inverse of a rank- r update is a rank- r update of the inverse.

³⁶We are pointing out that in part of the literature, notably in [Nocedal, Wright, 2006](#), the notations for B and H are reversed.

Proof. Suppose first that $C^{-1} + VA^{-1}U$ is non-singular. Then it can be checked straightforwardly that the inverse of $A + UC V$ is given by the right-hand side in (5.58). For the converse statement, we can reverse the roles as follows:

$$A \leftrightarrow C^{-1}, \quad C \leftrightarrow A^{-1}, \quad V \leftrightarrow U, \quad U \leftrightarrow V.$$

□

Dropping indices, the update formulas we discussed in (5.46) are of the form

$$H^+ = \Phi(H, s, y).$$

We will obtain update formulas for the inverse of the form

$$B^+ = \Psi(B, s, y)$$

with the property that $B = H^{-1}$ implies $B^+ = (H^+)^{-1}$. Since Φ_{DFP} and Φ_{BFGS} are expressed in terms of rank-2 updates of the input H , the [Sherman-Morrison-Woodbury lemma 5.50](#) allows us to express also Ψ_{DFP} and Ψ_{BFGS} in terms of rank-2 update formulas. Indeed, we can obtain the

- **inverse DFP quasi-Newton update:**

The Sherman-Morrison-Woodbury formula applied to the DFP update formula (5.53) yields

$$\Psi_{\text{DFP}}(B, s, y) = B - \frac{B y y^T B}{y^T B y} + \rho s s^T \quad (5.59)$$

where, again, $\rho = 1/(y^T s)$.

- **inverse BFGS quasi-Newton update:**

Similarly, we can obtain

$$\begin{aligned} \Psi_{\text{BFGS}}(B, s, y) &= (\text{Id} - \rho s y^T) B (\text{Id} - \rho y s^T) + \rho s s^T \\ &= B + \rho (s - B y) s^T + \rho s (s - B y)^T - \rho^2 (s - B y)^T y s^T, \end{aligned} \quad (5.60)$$

cf. [homework problem 6.4](#). Interestingly, it turns out that the DFP and BFGS updates are **inverse** to each other. More precisely, we have

$$\Psi_{\text{DFP}}(\cdot, s, y) = \Phi_{\text{BFGS}}(\cdot, y, s) \quad \text{and} \quad \Psi_{\text{BFGS}}(\cdot, s, y) = \Phi_{\text{DFP}}(\cdot, y, s). \quad (5.61)$$

Using an inverse quasi-Newton formula and obtaining the quasi-Newton direction from (5.57) solves both issues with Newton's method identified in the beginning of § 5.5. In the literature, the BFGS update is reported to be generally the most efficient among the quasi-Newton updates. For completeness, we therefore now state a globalized algorithm using the inverse BFGS update.

Algorithm 5.51 (Globalized quasi-Newton method with inverse BFGS update for (UP)).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: routine to evaluate f and f' (or ∇f)

Input: routine that implements the inverse BFGS update Ψ_{BFGS}

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Input: Armijo and curvature parameters $0 < \sigma < \tau < 1$ with $\sigma \in (0, 1/2)$ // to be passed through to the Wolfe-Powell line search

Input: expansion parameter $\gamma > 1$ // to be passed through to the Wolfe-Powell line search

Input: nesting parameters $\underline{\gamma}, \bar{\gamma} \in (0, 1/2]$ // to be passed through to the Wolfe-Powell line search

Output: approximately stationary point of (UP)

1: Setze $k := 0$

2: Setze $f^{(0)} := f(x^{(0)})$

3: Setze $r^{(0)} := f'(x^{(0)})^\top = \nabla f(x^{(0)})$

4: Setze $d_G^{(0)} := -M^{-1}r^{(0)}$

5: Setze $\delta^{(0)} := -(r^{(0)})^\top d_G^{(0)}$ // $\delta^{(0)} = \|\nabla_M f(x^{(0)})\|_M^2 = \|d_G^{(0)}\|_M^2$

Input: Set $B_{\text{BFGS}}^{(0)} := M^{-1}$ // initial model Hessian equals the user-defined base metric

6: **while** stopping criterion not met **do**

7: Determine the quasi-Newton direction $d^{(k)}$ from

$$d^{(k)} := -B_{\text{BFGS}}^{(k)} \nabla f(x^{(k)})$$

8: Determine a step size $\alpha^{(k)} > 0$ from a Wolfe-Powell line search procedure (Algorithm 5.18), applied to $\varphi(\alpha) := f(x^{(k)} + \alpha d^{(k)})$, with initial trial step size $\alpha^{(k,0)}$, Armijo parameter σ , curvature parameter τ , expansion parameter γ and nesting parameters $\underline{\gamma}, \bar{\gamma}$ // $\varphi(0) = f^{(k)}$ is already known and $\varphi'(0) = (r^{(k)})^\top d^{(k)}$ is easily evaluated

9: Set $s^{(k)} := \alpha^{(k)} d^{(k)}$

10: Set $x^{(k+1)} := x^{(k)} + s^{(k)}$

11: Set $f^{(k+1)} := f(x^{(k+1)})$

12: Set $r^{(k+1)} := f'(x^{(k+1)})^\top = \nabla f(x^{(k+1)})$

13: Set $d_G^{(k+1)} := -M^{-1}r^{(k+1)}$

// evaluate the negative M-gradient

14: Set $\delta^{(k+1)} := -(r^{(k+1)})^\top d_G^{(k+1)}$

// $\delta^{(k+1)} = \|\nabla_M f(x^{(k+1)})\|_M^2 = \|d_G^{(k+1)}\|_M^2$

15: Set $y^{(k)} := r^{(k+1)} - r^{(k)}$

16: Evaluate $B_{\text{BFGS}}^{(k+1)} := \Psi_{\text{BFGS}}(B_{\text{BFGS}}^{(k)}, s^{(k)}, y^{(k)})$

17: Set $k := k + 1$

18: **end while**

19: **return** $x^{(k)}$

Remark 5.52 (on Algorithm 5.51).

(i) The choice $B_{\text{BFGS}}^{(0)} = M^{-1}$ lends itself as the inverse of the initial model Hessian. In this way, the user-defined base metric M serves as the initial model Hessian, as in gradient descent methods. However, in contrast to gradient descent methods, the metric then evolves according to the data $s^{(k)}$ and $y^{(k)}$ acquired throughout the iterations.

(ii) Unfortunately, the convergence results for Algorithm 5.51 are not as rich as for other methods.

- One can show the local Q -superlinear convergence of $x^{(k)}$ to a point x^* satisfying the second-order sufficient optimality condition (see Theorem 3.3), provided that $x^{(0)}$ is sufficiently close

to x^* , the step sizes are fixed to $\alpha^{(k)} = 1$, and the initial Hessian M is sufficiently close to $f''(x^*)$.

- Global convergence can be proved under the assumption that the generalized condition numbers of the inverse BFGS matrices $B_{\text{BFGS}}^{(k)}$ w.r.t. M^{-1} remains bounded. This is equivalent to the generalized condition numbers of the (non-inverse) BFGS matrices $H_{\text{BFGS}}^{(k)}$ w.r.t. M remaining bounded. (**Quiz 5.9:** Can you see why this is equivalent?)

Under this assumption, [Lemma 5.5](#) ensures that the angle condition holds, and thus the search directions are admissible ([Lemma 5.4](#)). Moreover, under the assumption that the sublevel set $\mathcal{M}_f(x^{(0)}) := \{x \in \mathbb{R}^n \mid f(x) \leq f(x^{(0)})\}$ is compact, the Wolfe-Powell step sizes can be shown to be admissible ([Ulbrich, Ulbrich, 2012, Satz 9.5](#)). The global convergence, in the sense that every accumulation point of the sequence of iterates $x^{(k)}$ is a stationary point, then follows from the [global convergence theorem 5.9](#). See [Ulbrich, Ulbrich, 2012, Satz 13.11](#) for details.

- Unfortunately, the boundedness of the (inverse) BFGS matrices' generalized condition numbers cannot be guaranteed a priori. One possible remedy is to introduce a generalized angle condition such as

$$f'(x^{(k)}) d^{(k)} \leq -\min\{\eta, \rho \|d_G^{(k)}\|_M^p\} \|d_G^{(k)}\|_M \|d^{(k)}\|_M \quad (5.27)$$

into [Algorithm 5.51](#). Due to the estimate

$$-f'(x^{(k)}) d \geq \frac{2\sqrt{\kappa}}{\kappa+1} \|d_G^{(k)}\|_M \|d\|_M$$

for all $d \in \mathbb{R}^n$ that we have from [Lemma 5.5](#), a violation of condition (5.27) either means that the residual norm $\|d_G^{(k)}\|_M = \|f'(x^{(k)})\|_{M^{-1}}$ has already become small (so that further convergence can be entrusted to the local convergence result), or it otherwise indicates run-away generalized condition numbers of $H^{(k)}$ w.r.t. M .³⁷

When (5.27) is violated, we might reset the matrix to $B_{\text{BFGS}}^{(k)} := B_{\text{BFGS}}^{(0)}$, discard and re-evaluate the current direction $d^{(k)}$, effectively resorting to a steepest descent step. Under these modifications of [Algorithm 5.51](#), the a priori assumption on the boundedness of the (inverse) BFGS matrices can be dropped in the proof of global convergence. For further details, see [Geiger, Kanzow, 1999, p.167](#) and the reference [Kosmol, 1989, Kapitel 11.5](#) they are citing.

- (iii) In practice, [Algorithm 5.51](#) often exhibits Q -superlinear convergence. This is remarkable since only first-order derivatives of f are being used.

LIMITED-MEMORY BFGS METHOD

While the quasi-Newton methods we discussed so far successfully avoid second-order derivatives of the objective and replace the solutions of linear systems by matrix-vector products to obtain the search

³⁷Notice that $\kappa \mapsto \frac{2\sqrt{\kappa}}{\kappa+1}$ is monotone decreasing and it goes to 0 if and only if $\kappa \rightarrow \infty$.

directions, one disadvantage remains. That issue is the high memory requirement to store the inverse quasi-Newton matrices $B^{(k)}$ (or their non-inverted counterparts $H^{(k)}$) when the problem dimension n is not small. For instance, a problem of the (still moderate) dimension $n = 10\,000$ already requires

$$\frac{n(n+1)}{2} \underbrace{8\text{ B}}_{\text{storage for one double precision number}} \approx 381\text{ MiB}$$

of storage, while a problem of size $n = 100\,000$ requires about 37 GiB.³⁸

Typically (but not always), the true Hessian f'' is sparse for large-scale problems. By contrast, the quasi-Newton matrices $H^{(k)}$ and their inverses $B^{(k)}$ are always fully populated, although their difference to their initial values $H^{(k)}$ and $B^{(k)}$ is at most of rank $2k$.

Two ideas can be used to solve the storage issue.

- (1) Instead of storing the matrices $B^{(k)}$ entry by entry, we only store the pairs of vectors

$$(y^{(0)}, s^{(0)}), (y^{(1)}, s^{(1)}), \dots$$

As we will see, this is sufficient to evaluate the matrix-vector products $B^{(k)}r$.

- (2) The above modification still requires us to store two additional vectors of length n per iteration. We can, however, limit the storage by keeping only the most recent m pairs of vectors and dropping the previous.

The combination of these ideas leads to **limited-memory quasi-Newton methods**. While the **limited-memory idea** is generally applicable to all low-rank quasi-Newton update formulas, we concentrate here on the inverse BFGS update. We start by reviewing the respective update formula (5.60), which leads to the recursion

$$B_{\text{BFGS}}^{(k+1)} = (V^{(k)})^\top B_{\text{BFGS}}^{(k)} V^{(k)} + \rho^{(k)} s^{(k)} (s^{(k)})^\top,$$

where $\rho^{(k)} := 1/(y^{(k)})^\top s^{(k)}$ and $V^{(k)} := \text{Id} - \rho^{(k)} y^{(k)} (s^{(k)})^\top$. Working out the first few elements of this sequence, we obtain

$$\begin{aligned} B_{\text{BFGS}}^{(1)} &= (V^{(0)})^\top B_{\text{BFGS}}^{(0)} V^{(0)} + \rho^{(0)} s^{(0)} (s^{(0)})^\top \\ B_{\text{BFGS}}^{(2)} &= (V^{(1)})^\top B_{\text{BFGS}}^{(1)} V^{(1)} + \rho^{(1)} s^{(1)} (s^{(1)})^\top \\ &= (V^{(1)})^\top (V^{(0)})^\top B_{\text{BFGS}}^{(0)} V^{(0)} V^{(1)} + \rho^{(0)} (V^{(1)})^\top s^{(0)} (s^{(0)})^\top V^{(1)} + \rho^{(1)} s^{(1)} (s^{(1)})^\top \end{aligned}$$

etc. We only need to evaluate matrix-vector products such as

$$B_{\text{BFGS}}^{(2)} r = (V^{(1)})^\top (V^{(0)})^\top B_{\text{BFGS}}^{(0)} V^{(0)} V^{(1)} r + \rho^{(0)} (V^{(1)})^\top s^{(0)} (s^{(0)})^\top V^{(1)} r + \rho^{(1)} s^{(1)} (s^{(1)})^\top r,$$

which can be realized efficiently as follows.

Algorithm 5.53 (Recursive evaluation of $B_{\text{BFGS}}^{(k)} r$).

³⁸A **Mebibyte** (MiB) are 2^{20} bytes, a **Gibibyte** (GiB) are 2^{30} bytes. The prefixes “mebi” and gibi replace the former “mega” und “giga”, which should however be reserved to mean 10^6 and 10^9 , respectively.

Input: initial matrix $B_{\text{BFGS}}^{(0)}$ (or matrix-vector products with $B_{\text{BFGS}}^{(0)}$)
Input: pairs of vectors $(y^{(i)}, s^{(i)})$ and scalars $\rho^{(i)} = 1/(y^{(i)})^\top s^{(i)}$ for $i = 0, \dots, k-1$
Input: vector $r \in \mathbb{R}^n$
Output: $B_{\text{BFGS}}^{(k)} r$

```

1: for  $i := k-1, k-2, \dots, 0$  do
2:   Set  $\alpha^{(i)} := \rho^{(i)} (s^{(i)})^\top r$ 
3:   Set  $r := r - \alpha^{(i)} y^{(i)}$ 
4: end for
5: Set  $d := B_{\text{BFGS}}^{(0)} r$ 
6: for  $i := 0, 1, \dots, k-1$  do
7:   Set  $\beta^{(i)} := \rho^{(i)} (y^{(i)})^\top d$ 
8:   Set  $d := d + (\alpha^{(i)} - \beta^{(i)}) s^{(i)}$ 
9: end for
10: return  $d$ 

```

$\parallel r \rightsquigarrow V^{(0)} V^{(1)} \dots V^{(k-1)} r$

$\parallel d = B_{\text{BFGS}}^{(k)} r$

Remark 5.54 (on Algorithm 5.53).

- (i) We do not need $B_{\text{BFGS}}^{(0)}$ as a matrix since only matrix-vector products with $B_{\text{BFGS}}^{(0)}$ are required.
- (ii) Using Algorithm 5.53, it is even possible to change the inverse base metric $B_{\text{BFGS}}^{(0)}$ during the run of the quasi-Newton algorithm. This is impossible when the update formula (5.60) is used to explicitly form the matrices $B_{\text{BFGS}}^{(k)}$.

We now come back to the second idea of limiting the storage of the pairs of vectors $(y^{(i)}, s^{(i)})$ to the m most recent ones.³⁹ This idea is easily incorporated into Algorithm 5.53. The resulting update rule is called the **inverse limited-memory BFGS update rule** or briefly, the **(inverse) L-BFGS** or **(inverse) LM-BFGS** rule.

Algorithm 5.55 (Recursive evaluation of $B_{\text{LM-BFGS}}^{(k)} r$).

Input: initial matrix $B_{\text{BFGS}}^{(0)}$ (or matrix-vector products with $B_{\text{BFGS}}^{(0)}$)
Input: pairs of vectors $(y^{(i)}, s^{(i)})$ and scalars $\rho^{(i)} = 1/(y^{(i)})^\top s^{(i)}$ for $i = k-m, \dots, k-1$
Input: vector $r \in \mathbb{R}^n$
Output: $B_{\text{BFGS}}^{(k)} r$

```

1: for  $i := k-1, k-2, \dots, k-m$  do
2:   Set  $\alpha^{(i)} := \rho^{(i)} (s^{(i)})^\top r$ 
3:   Set  $r := r - \alpha^{(i)} y^{(i)}$ 
4: end for
5: Set  $d := B_{\text{BFGS}}^{(0)} r$ 
6: for  $i := k-m, k-m-1, \dots, k-1$  do
7:   Set  $\beta^{(i)} := \rho^{(i)} (y^{(i)})^\top d$ 
8:   Set  $d := d + (\alpha^{(i)} - \beta^{(i)}) s^{(i)}$ 
9: end for
10: return  $d$ 

```

$\parallel r \rightsquigarrow V^{(k-m)} V^{(k-m-1)} \dots V^{(k-1)} r$

$\parallel d = B_{\text{BFGS}}^{(k)} r$

³⁹We do not relabel the vectors.

We conclude with some remarks on limited-memory quasi-Newton methods.

Remark 5.56 (on limited-memory quasi-Newton methods).

(i) *During the first iterations, the number of vectors pairs is gradually increased until the desired size m_{\max} of the storage window is reached. That is, we use $m = \min\{k, m_{\max}\}$. Typically, $3 \leq m_{\max} \leq 10$ holds.*

(ii) *The modifications in Algorithm 5.51 in order to use the inverse limited-memory BFGS update rather than the full (unlimited) inverse BFGS update are minor. In Line 7, we obtain the quasi-Newton direction by evaluating*

$$d^{(k)} = -B_{\text{LM-BFGS}}^{(k)} \nabla f(x^{(k)})$$

using Algorithm 5.55. The evaluation of the next inverse model Hessian $B_{\text{LM-BFGS}}^{(k+1)}$ in Line 16 is replaced by adding the most recent vector pair $(y^{(k)}, s^{(k)})$ to the storage.

(iii) *We cannot expect a limited-memory quasi-Newton method to converge Q-superlinearly in general.*

§ 5.8 NONLINEAR CONJUGATE GRADIENT METHODS

Let us recap the contents of § 5 up to here. After introducing the general framework of line search methods, we discussed a first example, the gradient descent method, in § 5.3. This makes do with first-order derivatives but does not yield Q-superlinear convergence in general. This led us to consider (inexact) Newton methods (§ 5.4, § 5.6), which achieve Q-superlinear or even Q-quadratic convergence but are more expensive due to the use of second-order derivatives and solving (albeit only inexactly) a linear systems with $f''(x^{(k)})$ in each iteration. As a compromise, we then introduced quasi-Newton methods (§ 5.7), which make do with first-order derivatives and are capable of achieving Q-superlinear convergence.

An alternative class of methods which also works with first-order derivatives only is based on the extension of the conjugate gradient (CG) method (§ 4.6) to nonlinear objective functions. These methods are known as **nonlinear conjugate gradient methods**.

The essential characteristics of the CG method for *quadratic* objectives were:

- (1) Every new search direction $d^{(k+1)}$ was obtained from the current search direction $d^{(k)}$ and the direction of steepest descent, by forming a linear combination such that $d^{(k)}$ and $d^{(k+1)}$ became A-orthogonal. The A-orthogonality with all previous search directions was automatic.
- (2) The Cauchy step size (exact minimizing step size) was taken along every search direction. This was possible due to the objective being a quadratic polynomial.

For nonlinear CG methods, we need to observe the following in comparison.

- (1) The Cauchy step size is no longer available. Instead, a line search procedure is used, which is often a strong Wolfe-Powell line search.

- (2) We continue to denote the residual as $r^{(k)} := \nabla f(x^{(k)})$.
- (3) Since the Hessian of the objective is no longer a constant, s. p. d. matrix A , the requirement of A -conjugate (A -orthogonal) search directions does not make sense anymore. However, one maintains the construction principle that every new search direction $d^{(k+1)}$ is obtained from a linear combination of the current search direction $d^{(k)}$ and the direction of steepest descent:

$$\begin{aligned} d^{(0)} &:= -M^{-1}r^{(0)} && \text{for } k = 0, \\ d^{(k)} &:= -M^{-1}r^{(k)} + \beta^{(k)} d^{(k-1)} && \text{for } k \geq 1. \end{aligned} \quad (4.23)$$

The coefficients β are obtained using any of the formulas in (4.24'), which are no longer equivalent for nonlinear CG methods but yield distinct methods; see Table 5.1.

Algorithm 5.57 (Generic nonlinear conjugate gradient method; compare Algorithm 4.17).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

Input: right-hand side $b \in \mathbb{R}^n$

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Output: approximately stationary point of (UP)

```

1: Set  $k := 0$ 
2: Set  $r^{(0)} := \nabla f(x^{(0)})$  // evaluate the initial residual
3: Set  $d^{(0)} := -M^{-1}r^{(0)}$  // evaluate the initial negative  $M$ -gradient
4: Set  $\delta^{(0)} := -(r^{(0)})^\top d^{(0)}$  //  $\delta^{(0)} = \|\nabla_M f(x^{(0)})\|_M^2$ 
5: while stopping criterion not met do
6:   Determine a step size  $\alpha^{(k)} > 0$  from an appropriate line search procedure
7:   // the details depend on the type of method (rule for choosing  $\beta$ )
8:   Set  $x^{(k+1)} := x^{(k)} + \alpha^{(k)} d^{(k)}$ 
9:   Set  $r^{(k+1)} := \nabla f(x^{(k+1)})$  // updating the residual is not possible
10:  Set  $d^{(k+1)} := -M^{-1}r_{k+1}$  // evaluate the negative  $M$ -gradient
11:  Set  $\delta_{k+1} := -(r_{k+1})^\top d^{(k+1)}$  //  $\delta^{(k+1)} = \|\nabla_M f(x^{(k+1)})\|_M^2 = \|r^{(k+1)}\|_{M^{-1}}^2$ 
12:  Set  $y^{(k)} := r^{(k+1)} - r^{(k)}$  // some nonlinear CG methods use this
13:  Determine  $\beta^{(k+1)}$  // different nonlinear CG methods differ here
14:  Set  $d^{(k+1)} := d^{(k+1)} + \beta^{(k+1)} d^{(k)}$  // obtain the new search direction
15:  Set  $k := k + 1$ 
16: end while
17: return  $x^{(k)}$ 

```

Different nonlinear CG methods differ with respect to the rule for choosing $\beta^{(k+1)}$. Altogether, we had seen in (4.24') the two expressions

$$(r^{(k+1)} - r^{(k)})^\top M^{-1} r^{(k+1)} \quad \text{and} \quad (r^{(k+1)})^\top M^{-1} r^{(k+1)} \quad (5.62)$$

for the numerator and the three expressions

$$(r^{(k+1)} - r^{(k)})^\top d^{(k)}, \quad -(r^{(k)})^\top d^{(k)} \quad \text{and} \quad (r^{(k)})^\top M^{-1} r^{(k)} \quad (5.63)$$

for the denominator.⁴⁰ All six combinations (as well as additional variants) appear in the literature and yield meaningful methods. Some prominent choices are summarized in Table 5.1. Some formulas use the abbreviation $y^{(k)} = \nabla f(x^{(k+1)}) - \nabla f(x^{(k)}) = r^{(k+1)} - r^{(k)}$ as in quasi-Newton methods.

The line search procedure should yield an approximately stationary point of the line search function $\varphi(\alpha) = f(x^{(k)} + \alpha d^{(k)})$. Typically, the strong Wolfe-Powell conditions are required for this purpose with a small curvature parameter such as $\tau = 10^{-1}$ or $\tau = 10^{-2}$. In the (theoretical) case of an exact line search, yielding an exactly stationary step size $\alpha^{(k)}$ of the line search function, we have $(r^{(k+1)})^\top d^{(k)} = f'(x^{(k+1)}) d^{(k)} = \varphi'(\alpha^{(k)}) = 0$. Moreover, we also have $(r^{(k)})^\top d^{(k-1)} = 0$ from the previous iteration, and therefore

$$(r^{(k+1)} - r^{(k)})^\top d^{(k)} = -(r^{(k)})^\top d^{(k)} = (r^{(k)})^\top (M^{-1} r^{(k)} - \beta^{(k)} d^{(k-1)}) = (r^{(k)})^\top M^{-1} r^{(k)}.$$

In this case, we see that the three different expressions in (5.63) for the denominator of $\beta^{(k+1)}$ coincide.

Convergence proofs for nonlinear CG methods are significantly more technical than for other methods, and we do not go into the details. It can be generally stated that the methods using $(r^{(k)})^\top M^{-1} r^{(k)}$ as numerator admit better convergence theories but that the methods using $(r^{(k)} - r^{(k-1)})^\top M^{-1} r^{(k)}$ are often faster in practice.

As a stopping criterion we can use again a relative and/or absolute criterion involving $r^{(k)} = \nabla f(x^{(k)})$, see (4.14).

End of Week 6

⁴⁰The expression $-(r^{(k)})^\top d^{(k)}$ was not explicitly given but can be derived immediately from (4.22), which implies $(r^{(k+1)} - r^{(k)})^\top d^{(k)} = -(r^{(k)})^\top d^{(k)}$.

| Name | Choice of $\beta^{(k+1)}$ | Remark |
|-------------------------|--|--|
| Hestenes–Stiefel (1952) | $\beta_{\text{HS}}^{(k+1)} = \frac{(y^{(k)})^T M^{-1} r^{(k+1)}}{(y^{(k)})^T d^{(k)}}$ | |
| Fletcher–Reeves (1964) | $\beta_{\text{FR}}^{(k+1)} = \frac{\ r^{(k+1)}\ _{M^{-1}}^2}{\ r^{(k)}\ _{M^{-1}}^2}$ | strong Wolfe-Powell conditions (5.12), (5.18) with $0 < \sigma < \tau < 1/2$ |
| Polak–Ribière (1969) | $\beta_{\text{PR}}^{(k+1)} = \frac{(y^{(k)})^T M^{-1} r^{(k+1)}}{\ r^{(k)}\ _{M^{-1}}^2}$ | no descent guaranteed, therefore often $\beta_{\text{PR}+}^{(k+1)} := \max\{0, \beta_{\text{PR}}^{(k+1)}\}$, where $\beta_{\text{PR}+}^{(k+1)} = 0 \hat{=}$ gradient descent step |
| Powell (1985) | $\beta_{\text{PR}+}^{(k+1)} = \max\{0, \beta_{\text{PR}}^{(k+1)}\}$ | refinement of the strong Wolfe-Powell conditions, see Gilbert, Nocedal, 1992, eq.(4.1) and section 6 |
| Fletcher (1987) | $\beta_{\text{F}}^{(k+1)} = \frac{\ r^{(k+1)}\ _{M^{-1}}^2}{-(r^{(k)})^T d^{(k)}}$ | |

Table 5.1: Some common nonlinear conjugate gradient methods.

§ 6 TRUST-REGION METHODS FOR NONLINEAR UNCONSTRAINED PROBLEMS

The line search methods from § 5 proceed by first determining a search direction $d^{(k)}$, by (inexactly) minimizing a quadratic model of the objective

$$q^{(k)}(d) = f(x^{(k)}) + f'(x^{(k)})d + \frac{1}{2}d^T H^{(k)}d \quad (5.2)$$

or by (inexactly) solving the linear system

$$H^{(k)}d^{(k)} = -\nabla f(x^{(k)}). \quad (5.4)$$

Subsequently, a suitable step size $\alpha^{(k)} > 0$ is determined and the iterate is updated according to

$$x^{(k+1)} := x^{(k)} + \underbrace{\alpha^{(k)} d^{(k)}}_{s^{(k)}}.$$

Trust-region methods, by contrast, determine the direction and the step size **simultaneously**. They generate the combined step $s^{(k)}$ as a (usually inexact) solution of the **trust-region subproblem**

$$\begin{aligned} \text{Minimize} \quad & q^{(k)}(s) = f(x^{(k)}) + f'(x^{(k)})s + \frac{1}{2}s^T H^{(k)}s, \quad \text{where } s \in \mathbb{R}^n \\ \text{subject to} \quad & \|s\|_M \leq \Delta^{(k)}. \end{aligned} \quad (6.1)$$

As for line search methods, $H^{(k)}$ is the model Hessian, which we require to be symmetric but not necessarily positive definite. The quantity $\Delta^{(k)} > 0$ is the **trust-region radius** governing the **trust region**

$$\{s \in \mathbb{R}^n \mid \|s\|_M \leq \Delta^{(k)}\}$$

attached to the quadratic model.

Note: At $s = 0$, the value of the model $q^{(k)}$ as well as its derivative agree with those of $s \mapsto f(x^{(k)} + s)$. In case of the Newton model ($H^{(k)} = f''(x^{(k)})$), the second derivatives agree as well. Either way, for small values of $\|s\|_M$, the model $q^{(k)}$ will be in good agreement with $s \mapsto f(x^{(k)} + s)$ by [Taylor's theorem 2.3](#).

Since the trust region is a compact set and the objective is continuous (in fact, infinitely smooth), problem (6.1) always has a global minimizer even when $H^{(k)}$ is not positive definite.

Analogously as in line search methods, trust-region algorithms need to monitor the quality of the step $s^{(k)}$, in order to obtain sufficient descent. In fact, we should rather speak of the **step proposal** $s^{(k)}$ because trust-region methods may reject the proposal. The basis of evaluation of the quality of a tentative step $s^{(k)}$ at the point $x^{(k)}$ is the comparison of the **actual reduction** in objective values

$$\text{ared}(x^{(k)}; s^{(k)}) := f(x^{(k)}) - f(x^{(k)} + s^{(k)}) \quad (6.2)$$

to the **predicted reduction** based on the model $q^{(k)}$ associated with the iterate $x^{(k)}$

$$\begin{aligned} \text{pred}(x^{(k)}; s^{(k)}) &:= q^{(k)}(0) - q^{(k)}(s^{(k)}) \\ &= f(x^{(k)}) - q^{(k)}(s^{(k)}) \\ &= -f'(x^{(k)})s^{(k)} - \frac{1}{2}(s^{(k)})^T H^{(k)}s^{(k)}. \end{aligned} \quad (6.3)$$

This comparison is achieved in terms of the ratio of these two quantities,

$$\rho(x^{(k)}; s^{(k)}) := \frac{\text{ared}(x^{(k)}; s^{(k)})}{\text{pred}(x^{(k)}; s^{(k)})}. \quad (6.4)$$

In our algorithms, we are going to produce only proposals satisfying

$$\text{pred}(x^{(k)}; s^{(k)}) > 0, \quad (6.5)$$

i. e., for which the model predicts a decrease. The actual decrease (6.2), however, can take either sign.

Suppose now that $s^{(k)}$ is an (inexact) solution of the trust-region subproblem (6.1). Based on the value of $\rho(x^{(k)}; s^{(k)})$, two decisions need to be taken:

- whether to accept or reject the step proposal $s^{(k)}$,
- how to choose the next the next trust-region radius.

These decisions usually depend on two algorithmic parameters $0 < \eta_1 < \eta_2 < 1$:

- (1) In case $\rho(x^{(k)}; s^{(k)}) < \eta_1$, the step proposal $s^{(k)}$ is considered **unsatisfactory**. The reason for this must be that the model $q^{(k)}$ does not coincide well with the true objective function f within the current trust region. In other words, the current trust region is too large.

We therefore reject and discard the step by setting $x^{(k+1)} := x^{(k)}$. We label this iterate **unsuccessful**.⁴¹ We also choose a new trust-region radius $\Delta^{(k+1)} < \Delta^{(k)}$. In fact, the new trust-region radius should even satisfy $\Delta^{(k+1)} < \|s^{(k)}\|_M$ in order to avoid computing the same unsuccessful step proposal again in the subsequent iteration.

- (2) In case $\rho(x^{(k)}; s^{(k)}) \geq \eta_1$, the step proposal $s^{(k)}$ is considered **satisfactory** and we accept it by setting $x^{(k+1)} := x^{(k)} + s^{(k)}$. The step is labeled **successful**. The trust region radius $\Delta^{(k+1)}$ for the subsequent step is chosen as follows.

- (a) In case $\rho(x^{(k)}; s^{(k)}) \geq \eta_2$, the coincidence between the predicted and actual reductions is considered **exceptionally good**. We can therefore allow the trust region for the next step to grow. However, this is sensible only if the current step $s^{(k)}$ actually did lie on the boundary of the trust region, i. e., when $\|s^{(k)}\|_M = \Delta^{(k)}$ holds.

- (b) Otherwise we keep the trust-region radius: $\Delta^{(k+1)} := \Delta^{(k)}$.

We may call η_1 the **acceptance threshold** and η_2 the **quality threshold**.

The above guidelines lead to the following generic trust-region method (Algorithm 6.1).

Algorithm 6.1 (Generic trust-region method).

Input: initial guess $x^{(0)} \in \mathbb{R}^n$

⁴¹We still count this as an iterate since essentially the same amount of work has been carried out as in a successful iterate.

Input: routine to evaluate f and f' (or ∇f)
Input: routine to construct the model Hessians $H^{(k)}$
Input: s. p. d. matrix M (or matrix-vector products with M^{-1})
Input: initial trust-region radius $\Delta^{(0)} > 0$
Input: trust-region step quality parameters $0 < \eta_1 < \eta_2 < 1$
Input: trust-region growth parameters $0 < \gamma_1 < 1 < \gamma_2$
Output: approximately stationary point of (UP)

```

1: Set  $k := 0$ 
2: Set  $f^{(0)} := f(x^{(0)})$  // evaluate the initial objective value
3: while stopping criterion not met do
4:   Determine a step proposal  $s^{(k)}$  by an inexact solution of the trust-region subproblem (6.1)
5:   Evaluate the ratio  $\rho(x^{(k)}; s^{(k)})$  according to (6.4)
6:   if  $\rho(x^{(k)}; s^{(k)}) \geq \eta_1$  then // satisfactory step proposal
7:     Set  $x^{(k+1)} := x^{(k)} + s^{(k)}$  // accept the step proposal
8:     Set  $f^{(k+1)} := f(x^{(k+1)})$ 
9:     if  $\rho(x^{(k)}; s^{(k)}) \geq \eta_2$  and  $\|s^{(k)}\|_M = \Delta^{(k)}$  then
10:       // exceptionally good step proposal and trust region too small
11:       Set  $\Delta^{(k+1)} := \gamma_2 \Delta^{(k)}$  // grow the trust region
12:     else // satisfactory but not exceptionally good step, or trust region sufficiently large
13:       Set  $\Delta^{(k+1)} := \Delta^{(k)}$  // keep the trust region
14:     end if
15:   else // unsatisfactory step proposal
16:     Set  $x^{(k+1)} := x^{(k)}$  // reject the step proposal
17:     Set  $f^{(k+1)} := f^{(k)}$ 
18:     Set  $\Delta^{(k+1)} := \gamma_1 \|s^{(k)}\|_M$  // shrink the trust region
19:   end if
20:   Set  $k := k + 1$ 
21: end while
22: return  $x^{(k)}$ 

```

Remark 6.2 (on Algorithm 6.1). The evaluation of the ratio $\rho(x^{(k)}; s^{(k)})$ requires

- one function evaluation $f(x^{(k)} + s^{(k)})$ and
- one model evaluation $q^{(k)}(s^{(k)}) = f(x^{(k)}) + f'(x^{(k)}) s^{(k)} + \frac{1}{2}(s^{(k)})^\top H^{(k)} s^{(k)}$

per iteration. If the step proposal is accepted, then $f(x^{(k)} + s^{(k)})$ becomes $f(x^{(k+1)})$, so that really only one evaluation of the objective f is required per iteration. The evaluation of $q^{(k)}(s^{(k)})$ is usually a by-product of the computation of the (inexact) solution of the trust-region subproblem (6.1).

In the remainder of this section we will consider the following questions.

- (1) Which requirements do we have to impose on Algorithm 6.1, in particular concerning the choice of model Hessians $H^{(k)}$ and the inexactness of the trust-region subproblem solves, in order to obtain global convergence? (§ 6.1)
- (2) How can we obtain fast local convergence? (§ 6.2)

- (3) What is a good algorithmic approach to solving the trust-region subproblems (6.1) with adjustable accuracy? (§ 6.3)

Assumption 6.3. Throughout § 6 we are assuming that $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is a C^1 function.

§ 6.1 GLOBAL CONVERGENCE

In line search methods, we used the angle condition to compare candidate search directions, such as the Newton direction in Algorithm 5.30 or the inexact Newton direction in Algorithm 5.44, to a reference direction. The steepest descent direction $d_G^{(k)}$ served as that reference and simultaneously as the fallback search direction. This was essential in establishing the global convergence.

A similar idea for trust-region methods uses as reference the **Cauchy point** or **Cauchy step** s_C . The Cauchy point is defined as the unique solution of the trust-region subproblem (6.1), but restricted to the subspace generated by the steepest descent direction. Dropping the iteration index for the time being, the **Cauchy point problem** reads

$$\begin{aligned} \text{Minimize} \quad & q(s) = f(x) + f'(x)s + \frac{1}{2} s^T H s, \quad \text{where } s \in \mathbb{R}^n, \tau \in \mathbb{R} \\ \text{subject to} \quad & \|s\|_M \leq \Delta^{(k)} \\ & \text{and } s = -\tau \nabla_M f(x). \end{aligned} \tag{6.6}$$

We assume $f'(x) \neq 0$. (**Quiz 6.1:** Why?) Abbreviating

$$g := \nabla_M f(x)$$

and reducing the problem to the variable τ by plugging in the constraint $s = -\tau \nabla_M f(x)$, we obtain the reduced Cauchy point problem

$$\begin{aligned} \text{Minimize} \quad & q(-\tau g) = f(x) - \tau \|g\|_M^2 + \frac{\tau^2}{2} g^T H g, \quad \text{where } \tau \in \mathbb{R} \\ \text{subject to} \quad & |\tau| \leq \frac{\Delta}{\|g\|_M}. \end{aligned} \tag{6.7}$$

This is the minimization of a univariate quadratic polynomial over a compact interval that is symmetric about 0. The solution of this problem is given in the following lemma.

Lemma 6.4 (Evaluation of the Cauchy point). *Suppose that $g \neq 0$ and $\Delta \geq 0$ hold. Then the unique solution $s_C = -\tau_C g$ of (6.10), respectively the unique solution τ_C of the reduced problem (6.7), is given by*

$$\tau_C = \begin{cases} \min \left\{ \frac{\|g\|_M^2}{g^T H g}, \frac{\Delta}{\|g\|_M} \right\}, & \text{if } g^T H g > 0, \\ \frac{\Delta}{\|g\|_M} & \text{otherwise.} \end{cases} \tag{6.8}$$

Therefore, the decrease predicted by the model at the Cauchy point s_C satisfies

$$\begin{aligned} \text{pred}(x; s_C) &= f(x) - q(s_C) \\ &\geq \frac{1}{2} \|g\|_M \min\left\{\Delta, \frac{\|g\|_M^3}{\max\{0, g^\top H g\}}\right\} \\ &\geq \frac{1}{2} \|g\|_M \min\left\{\Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}}\right\}, \end{aligned} \quad (6.9)$$

where we interpret $\frac{\|g\|_M^3}{0}$ and $\frac{\|g\|_M}{0}$ as $+\infty$.

Proof. We denote the objective in (6.7), which is a univariate quadratic polynomial, by

$$\varphi(\tau) := f(x) - \tau \|g\|_M^2 + \frac{\tau^2}{2} g^\top H g.$$

For any $\tau \in \mathbb{R}$ and $s = -\tau g$, we have

$$\text{pred}(x; s) = f(x) - q(-\tau g) = f(x) - \varphi(\tau) = \tau \|g\|_M^2 - \frac{\tau^2}{2} g^\top H g. \quad (*)$$

We need to distinguish two cases to find the optimal value for τ .

Case 1: $g^\top H g > 0$ (φ is strongly convex)

The derivative of φ is equal to zero precisely at

$$\tau^* = \frac{\|g\|_M^2}{g^\top H g} > 0.$$

In case this value is feasible, it is the unique solution of (6.7). Otherwise, due to $\varphi'(0) = -\tau \|g\|_M^2 < 0$, φ' is negative on the entire interval $[0, \frac{\Delta}{\|g\|_M}]$, and therefore φ is decreasing on this interval. Consequently, the maximal feasible value $\tau = \frac{\Delta}{\|g\|_M}$ is the unique solution of (6.7). To summarize this case:

$$\tau_C = \min\left\{\frac{\|g\|_M^2}{g^\top H g}, \frac{\Delta}{\|g\|_M}\right\}.$$

In order to evaluate $\text{pred}(x; s_C)$, we obtain from (*):

$$\begin{aligned} \text{pred}(x; s_C) &= \tau_C \|g\|_M^2 - \frac{\tau_C^2}{2} g^\top H g \\ &= \begin{cases} \frac{1}{2} \frac{\|g\|_M^4}{g^\top H g} = \frac{1}{2} \|g\|_M \frac{\|g\|_M^3}{\max\{0, g^\top H g\}} & \text{if } \tau_C = \frac{\|g\|_M^2}{g^\top H g} \leq \frac{\Delta}{\|g\|_M}, \\ \tau_C \left[\|g\|_M^2 - \frac{1}{2} \left[\frac{\Delta}{\|g\|_M} \right] g^\top H g \right] & \text{if } \tau_C = \frac{\Delta}{\|g\|_M} \leq \frac{\|g\|_M^2}{g^\top H g}. \end{cases} \end{aligned}$$

In the first case, (6.9) is satisfied since clearly

$$\frac{1}{2} \|g\|_M \frac{\|g\|_M^3}{\max\{0, g^\top H g\}} \geq \frac{1}{2} \|g\|_M \min\left\{\Delta, \frac{\|g\|_M^3}{\max\{0, g^\top H g\}}\right\}$$

holds. Moreover, due to (2.12), we have $\lambda_{\max}(H; M) \geq \frac{g^T H g}{\|g\|_M^2} > 0$ and therefore

$$\cdots \geq \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}} \right\}.$$

In the second case, we have

$$\begin{aligned} \tau_C \left[\|g\|_M^2 - \frac{1}{2} \left[\frac{\Delta}{\|g\|_M} \right] g^T H g \right] &\geq \tau_C \left[\|g\|_M^2 - \frac{1}{2} \left[\frac{\|g\|_M^2}{g^T H g} \right] g^T H g \right] \\ &= \frac{1}{2} \tau_C \|g\|_M^2 \\ &= \frac{1}{2} \Delta \|g\|_M \\ &\geq \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M^3}{\max\{0, g^T H g\}} \right\} \\ &= \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}} \right\}, \end{aligned}$$

so (6.9) also holds here.

Case 2: $g^T H g \leq 0$ (φ is concave)

Since φ is now concave, the solution τ_C of (6.7) must lie on the boundary of the feasible interval. In view of $\varphi'(0) = -\tau \|g\|_M^2 < 0$, we have

$$\tau_C = + \frac{\Delta}{\|g\|_M}.$$

Therefore, we obtain

$$\begin{aligned} \text{pred}(x; s_C) &= \Delta \|g\|_M + \frac{1}{2} \left[\frac{\Delta}{\|g\|_M} \right]^2 |g^T H g| \\ &\geq \Delta \|g\|_M \\ &\geq \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M^3}{\max\{0, g^T H g\}} \right\} \\ &\geq \frac{1}{2} \|g\|_M \min \{ \Delta, \infty \} \\ &= \frac{1}{2} \|g\|_M \Delta \\ &\geq \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}} \right\}, \end{aligned}$$

so (6.9) holds again. □

In order to formulate a condition on the step proposals $s^{(k)}$ that ensures the global convergence of the general trust-region method (Algorithm 6.1), we compare

- the decrease in the current model $\text{pred}(x^{(k)}; s^{(k)})$ obtained by the **proposed step** $s^{(k)}$
- with the decrease in the model $\text{pred}(x^{(k)}; s_C^{(k)})$ obtained by the **Cauchy step** $s_C^{(k)}$.

We require that $s^{(k)}$ realizes at least a fixed fraction of the decrease obtained by $s_C^{(k)}$. In fact, it will be sufficient that $s^{(k)}$ realizes a fixed fraction of the lower bound (6.9).

Definition 6.5 (Fraction of Cauchy decrease condition).

Consider the trust-region subproblem

$$\begin{aligned} \text{Minimize} \quad & q(s) = f(x) + f'(x)s + \frac{1}{2}s^T H s, \quad \text{where } s \in \mathbb{R}^n \\ \text{subject to} \quad & \|s\|_M \leq \Delta \end{aligned} \tag{6.10}$$

with $f'(x) \neq 0$ and thus also $g := \nabla_M f(x) \neq 0$. The Cauchy step for (6.10) is denoted by s_C .

- (i) A vector $s \in \mathbb{R}^n$ satisfies the **fraction of Cauchy decrease condition** for (6.10) if there exists a constant $\underline{C} \in (0, 1]$ such that

$$\text{pred}(x; s) \geq \underline{C} \text{pred}(x; s_C) \tag{6.11}$$

holds.

- (ii) A vector $s \in \mathbb{R}^n$ satisfies the **weak fraction of Cauchy decrease condition** for (6.10) if there exists a constant $\underline{C} \in (0, 1]$ such that

$$\text{pred}(x; s) \geq \underline{C} \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}} \right\} \tag{6.12}$$

holds.

Note: By (6.9), the fraction of Cauchy decrease condition (6.11) implies the weak fraction of Cauchy decrease condition (6.12). Moreover, the weak fraction of Cauchy decrease condition (6.12) implies that an accepted step size proposal satisfies

$$\begin{aligned} f(x) - f(x+s) &= \text{ared}(x; s) \\ &= \rho(x; s) \text{pred}(x; s) \quad \text{by definition of the ratio } \rho(\cdot; \cdot) \\ &\geq \eta_1 \text{pred}(x; s) \quad \text{since the step proposal was accepted} \\ &> 0 \quad \text{by (6.12).} \end{aligned}$$

In particular, any trust-region method that falls into the framework of [Algorithm 6.1](#) is a **descent method**.

Our proof of global convergence requires (roughly) the following auxiliary results to be shown:

- (1) The weak fraction of Cauchy decrease condition implies that [Algorithm 6.1](#) cannot get stuck in an infinite sequence of consecutively rejected steps ([Lemma 6.6](#) and [Corollary 6.7](#)).
- (2) If the sequence of function values $f(x^{(k)})$ is bounded below, then any subsequence of successful steps, whose associated trust-region radii $\Delta^{(k)}$ sum up to ∞ , is a sequence of vanishing gradients ([Lemma 6.8](#)).

We now show that for sufficiently small trust-region radius, step proposals satisfying the (weak) fraction of Cauchy decrease condition will always be successful. This result even holds uniformly for an entire class of trust-region subproblems.

Lemma 6.6 (Any acceptance threshold is achievable for small trust-region radius). *Suppose that $\bar{x} \in \mathbb{R}^n$ is a point satisfying $f'(\bar{x}) \neq 0$. Suppose, moreover, that $\eta_1 \in (0, 1)$ and $\underline{C} > 0$ and $\bar{H} > 0$ are given. Then there exist $\delta > 0$ and $\bar{\Delta} > 0$ such that the following holds: for any trust-region subproblem*

$$\begin{aligned} & \text{Minimize} \quad f(x) + f'(x)s + \frac{1}{2}s^\top Hs, \quad \text{where } s \in \mathbb{R}^n \\ & \text{subject to} \quad \|s\|_M \leq \Delta \end{aligned}$$

with data $x \in B_\delta^M(\bar{x})$ and $\Delta \in (0, \bar{\Delta}]$ and H symmetric with $\|H\|_{M^{-1} \leftarrow M} \leq \bar{H}$, any step proposal s that is feasible and satisfies the weak fraction of Cauchy decrease condition

$$\text{pred}(x; s) \geq \underline{C} \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}} \right\} \quad (6.12)$$

achieves a ratio $\rho(x; s) \geq \eta_1$.

Proof. The ratio under consideration satisfies

$$\rho(x; s) = \frac{\text{ared}(x; s)}{\text{pred}(x; s)} = 1 - \frac{\text{pred}(x; s) - \text{ared}(x; s)}{\text{pred}(x; s)}.$$

In order to show that it is $> \eta_1$ we need to estimate the numerator of the fraction from above and the denominator from below.

We begin with the denominator. Since f' is continuous, we can find $\delta > 0$ such that

$$\|g\|_M = \|\nabla_M f(x)\|_M \geq \frac{\|\nabla_M f(\bar{x})\|_M}{2} =: \varepsilon$$

holds for all $x \in B_\delta^M(\bar{x})$. We now set $\bar{\Delta} := \varepsilon/\bar{H}$ and consider a trust-region problem with data as specified in the statement of the lemma. Then we have

$$\Delta \leq \bar{\Delta} = \frac{\varepsilon}{\bar{H}} = \frac{\|\nabla_M f(\bar{x})\|_M}{2\bar{H}} \leq \frac{\|\nabla_M f(x)\|_M}{\bar{H}} = \frac{\|g\|_M}{\bar{H}} \leq \begin{cases} \frac{\|g\|_M}{\lambda_{\max}(H; M)}, & \text{in case } \lambda_{\max}(H; M) > 0 \\ \infty & \text{in case } \lambda_{\max}(H; M) \leq 0. \end{cases}$$

Notice that we have used (2.13) to infer $\lambda_{\max}(H; M) \leq \|H\|_{M^{-1} \leftarrow M} \leq \bar{H}$ in the last inequality. By the weak fraction of Cauchy decrease condition, we therefore conclude

$$\begin{aligned} \text{pred}(x; s) & \geq \underline{C} \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\max\{0, \lambda_{\max}(H; M)\}} \right\} \\ & \geq \underline{C} \frac{1}{2} \|g\|_M \min \left\{ \Delta, \frac{\|g\|_M}{\bar{H}} \right\} \end{aligned} \quad (6.13a)$$

$$= \underline{C} \frac{1}{2} \|g\|_M \Delta. \quad (6.13b)$$

For the numerator, we can estimate

$$\begin{aligned}
& \text{pred}(x; s) - \text{ared}(x; s) \\
&= -f'(x) s - \frac{1}{2} s^\top H s - [f(x) - f(x+s)] && \text{see (6.3)} \\
&= -f'(x) s - \frac{1}{2} s^\top H s + f'(x + \xi s) s && \text{by Taylor's theorem 2.4} \\
&\leq \|f'(x + \xi s) - f'(x)\|_{M^{-1}} \|s\|_M - \frac{1}{2} \lambda_{\min}(H; M) \|s\|_M^2 && \text{by (2.3) and (2.12)} \\
&\leq \|f'(x + \xi s) - f'(x)\|_{M^{-1}} \Delta + \frac{1}{2} \bar{H} \Delta^2 && \text{by (2.13) and } \|s\|_M \leq \Delta.
\end{aligned}$$

Notice that $x + \xi s$ and x are both close to \bar{x} , namely

$$\|x + \xi s - \bar{x}\|_M \leq \delta + \Delta \leq \delta + \bar{\Delta} \quad \text{and} \quad \|x - \bar{x}\|_M \leq \delta.$$

Using the continuity of f' and reducing δ and $\bar{\Delta}$ if necessary, we can thus achieve

$$\|f'(x + \xi_k s) - f'(x)\|_{M^{-1}} + \frac{1}{2} \bar{H} \Delta \leq \frac{1}{2} (1 - \eta_1) \subseteq \varepsilon.$$

This allows us to continue the estimate above as follows,

$$\begin{aligned}
\text{pred}(x; s) - \text{ared}(x; s) &\leq \|f'(x + \xi_k s) - f'(x)\|_{M^{-1}} \Delta + \frac{1}{2} \bar{H} \Delta^2 \\
&\leq \frac{1}{2} (1 - \eta_1) \subseteq \varepsilon \Delta \\
&\leq \frac{1}{2} (1 - \eta_1) \subseteq \|g\|_M \Delta.
\end{aligned}$$

Combining this with the estimate (6.13) of the denominator, we conclude

$$\rho(x; s) = 1 - \frac{\text{pred}(x; s) - \text{ared}(x; s)}{\text{pred}(x; s)} \geq 1 - \frac{\frac{1}{2} (1 - \eta_1) \subseteq \|g\|_M \Delta}{\subseteq \frac{1}{2} \|g\|_M \Delta} = \eta_1. \quad \square$$

The result of Lemma 6.6 immediately implies that Algorithm 6.1 produces infinitely many successful step proposals, provided that it does not stop with $f'(x^{(k)}) = 0$ and that the model Hessians remain bounded.

Corollary 6.7 (Infinitely many successful step proposals). *Suppose that the iterates $x^{(k)}$ of Algorithm 6.1 satisfy $f'(x^{(k)}) \neq 0$ and that the model Hessians $H^{(k)}$ are symmetric with $\|H^{(k)}\|_{M^{-1} \leftarrow M} \leq \bar{H}$. Moreover, suppose that the step proposals $s^{(k)}$ are feasible and satisfy the weak fraction of Cauchy decrease condition (6.12). Then there exist infinitely many indices k satisfying $\rho(x^{(k)}; s^{(k)}) \geq \eta_1$, i. e., the step proposal will be accepted.*

Note: In particular, a successful step can only be followed by finitely many unsuccessful steps.

Proof. We proceed by way of contradiction. Suppose the opposite, i. e., that $\rho(x^{(k)}; s^{(k)}) < \eta_1$ holds for all $k \geq k_0$. This means that from a certain iterate onwards, all step proposals will be rejected. By the logic of [Algorithm 6.1](#), see [Line 18](#), this implies

$$\Delta^{(k+1)} := \gamma_1 \|s^{(k)}\|_M \leq \gamma_1 \Delta^{(k)}$$

for all $k \geq k_0$ and thus $\Delta^{(k)} \rightarrow 0$. Moreover, the iterates $x^{(k)}$ and model Hessians $H^{(k)}$ remain constant for $k \geq k_0$. In particular, the entire sequence $(H^{(k)})$ is bounded. The subproblems (6.1) thus satisfy the prerequisites of [Lemma 6.6](#).⁴² This entails that, no matter how close the acceptance threshold η_1 is to 1, as soon as the trust-region radius $\Delta^{(k)}$ has become sufficiently small, we will have $\rho(x^{(k)}; s^{(k)}) \geq \eta_1$ and the step proposal will be accepted. This is in contradiction with our assumption. \square

We proceed to show [Statement \(2\)](#).

Lemma 6.8. *Suppose that the iterates $x^{(k)}$ of [Algorithm 6.1](#) satisfy $f'(x^{(k)}) \neq 0$ and that the model Hessians $H^{(k)}$ are symmetric with $\|H^{(k)}\|_{M^{-1} \leftarrow M} \leq \bar{H}$. Assume that the sequence of objective values $f(x^{(k)})$ is bounded below by f . Moreover, suppose that the step proposals $s^{(k)}$ satisfy the weak fraction of Cauchy decrease condition (6.12). If $K \subseteq \mathbb{N}_0$ is any (finite or infinite) index set of successful steps such that $\|g^{(k)}\|_M \geq \varepsilon > 0$ holds, then the associated trust-region radii are summable:*

$$\sum_{k \in K} \Delta^{(k)} < \infty.$$

Proof. For any index $k \in K$ we have by assumption $\rho(x^{(k)}; s^{(k)}) \geq \eta_1$ and thus

$$\begin{aligned} f(x^{(k)}) - f(x^{(k+1)}) &= \text{ared}(x^{(k)}; s^{(k)}) \\ &\geq \eta_1 \text{pred}(x^{(k)}; s^{(k)}) \\ &\geq \eta_1 \underline{C} \frac{1}{2} \|g^{(k)}\|_M \min\left\{\Delta^{(k)}, \frac{\|g^{(k)}\|_M}{\bar{H}}\right\} \quad \text{as in (6.13a)} \\ &\geq \eta_1 \underline{C} \frac{1}{2} \varepsilon \min\left\{\Delta^{(k)}, \frac{\varepsilon}{\bar{H}}\right\} \quad \text{by assumption.} \end{aligned}$$

Since the function values $f(x^{(k)})$ are monotone decreasing and, by assumption, bounded below, we must have

$$\sum_{k \in K} \eta_1 \underline{C} \frac{1}{2} \varepsilon \min\left\{\Delta^{(k)}, \frac{\varepsilon}{\bar{H}}\right\} < \infty.$$

⁴²We can use $\bar{x} = x^{(k_0)}$ and we do not need the variation in x .

More precisely, let k_{\min} be the smallest index in K , then we have

$$\begin{aligned}
& \sum_{k \in K} \eta_1 \subseteq \frac{1}{2} \varepsilon \min \left\{ \Delta^{(k)}, \frac{\varepsilon}{\bar{H}} \right\} \\
& \leq \sum_{k \in K} f(x^{(k)}) - f(x^{(k+1)}) \\
& \leq \sum_{k=k_{\min}}^{\infty} f(x^{(k)}) - f(x^{(k+1)}) \quad \text{all summands are } \geq 0 \text{ and a superset of the above} \\
& \leq f(x^{(k_{\min})}) - \underline{f} \quad \text{since } f(x^{(k)}) \geq \underline{f} \text{ for all } k \in \mathbb{N}_0 \\
& < \infty.
\end{aligned}$$

This implies the claim. □

With [Statements \(1\)](#) and [\(2\)](#) in place, we can now prove a global convergence theorem for [Algorithm 6.1](#).

Theorem 6.9 (Global convergence of model [Algorithm 6.1](#)). *Suppose that the model Hessians $H^{(k)}$ in [Algorithm 6.1](#) are symmetric with $\|H^{(k)}\|_{M^{-1} \leftarrow M} \leq \bar{H}$. Assume that the sequence of objective values $f(x^{(k)})$ is bounded below by \underline{f} . Moreover, suppose that the step proposals $s^{(k)}$ are feasible and satisfy the weak fraction of Cauchy decrease condition [\(6.12\)](#). Then the following holds.*

(1) [Algorithm 6.1](#) either terminates after finitely many iterations due to $f'(x^{(k)}) = 0$, or else we have⁴³

$$\liminf_{k \rightarrow \infty} \|f'(x^{(k)})\|_{M^{-1}} = 0. \quad (6.14)$$

(2) Suppose in addition that f' is uniformly continuous on the set of iterates $\{x^{(k)} \mid k \in \mathbb{N}_0\}$.⁴⁴ Then [Algorithm 6.1](#) either terminates after finitely many iterations due to $f'(x^{(k)}) = 0$, or else we have

$$\lim_{k \rightarrow \infty} f'(x^{(k)}) = 0. \quad (6.15)$$

Note: Statement [\(6.15\)](#) implies that all accumulation points of $(x^{(k)})$ are stationary points. **Quiz 6.2:** Details?

Proof. [Statement \(1\)](#): Assume that [Algorithm 6.1](#) does not terminate, i. e., we have $f'(x^{(k)}) \neq 0$ for all iterates. Suppose that [\(6.14\)](#) does not hold. This means that there exists $\varepsilon_1 > 0$ such that $g^{(k)} := \nabla_M f(x^{(k)})$ satisfies $\|g^{(k)}\|_M \geq \varepsilon_1$ for all $k \geq k_0$. Let $S \subseteq \mathbb{N}_0$ denote the index set of successful step proposals. This index set is infinite by [Corollary 6.7](#). From [Lemma 6.8](#), we further obtain

$$\sum_{k \in S} \Delta^{(k)} < \infty. \quad (*)$$

⁴³Statement [\(6.14\)](#) means that there exists a subsequence $(x^{(k)})_{k \in K}$ such that $f'(x^{(k)}) \xrightarrow{k \in K} 0$.

⁴⁴Unlike in the proof of, e. g., [Lemma 5.13](#), we cannot deduce the uniform continuity since the sequence $x^{(k)}$ is not necessarily bounded.

This implies in particular $\Delta^{(k)} \xrightarrow{k \in S} 0$.

Step (1) We show that $x^{(k)}$ is a Cauchy sequence.

Let $k > \ell \geq 0$ be any two indices. Then

$$\begin{aligned} \|x^{(k)} - x^{(\ell)}\|_M &\leq \sum_{\substack{j=\ell \\ j \in S}}^{k-1} \|s^{(j)}\|_M \quad \text{unsuccessful steps do not move } x \\ &\leq \sum_{\substack{j=\ell \\ j \in S}}^{k-1} \Delta^{(j)} \leq \sum_{\substack{j=\ell \\ j \in S}}^{\infty} \Delta^{(j)} \leq \sum_{j \in S} \Delta^{(j)}. \end{aligned}$$

The last sum is finite by (*). Therefore, the tails of this series (“Reihenreste”) $\sum_{\substack{j=\ell \\ j \in S}}^{\infty} \Delta^{(j)}$ converge to 0 as $\ell \rightarrow \infty$. This shows that $x^{(k)}$ is a Cauchy sequence.

Step (2) We show that $(\Delta^{(k)})_{k \geq L}$ is bounded away from 0.

$x^{(k)}$ has been shown to be a Cauchy sequence, hence it converges to some \bar{x} . The continuity of f' and $\|g^{(k)}\|_M \geq \varepsilon_1$ for all $k \geq k_0$ imply $\|\nabla_M f'(\bar{x})\|_M \geq \varepsilon_1$. We now apply Lemma 6.6 with η_2 (the quality threshold) in place of η_1 (the acceptance threshold). It shows that there exists $\bar{\Delta}$ and an index $L \in \mathbb{N}_0$ such that $\rho(x^{(k)}; s^{(k)}) \geq \eta_2$ holds for all indices $k \geq L$ (such that $x^{(k)}$ is close enough to \bar{x}) satisfying $\Delta^{(k)} \leq \bar{\Delta}$.

We now show, by way of induction, that

$$\Delta^{(k)} \geq \min\{\Delta^{(L)}, \gamma_1 \bar{\Delta}\} \quad \text{for all } k \geq L \quad (**)$$

holds, so that indeed the trust-region radii are bounded away from 0. Claim (**) holds trivially for $k = L$. As induction hypothesis, suppose that (**) is true for some $k \geq L$. In the induction step, we distinguish two cases. In case $\Delta^{(k)} \leq \bar{\Delta}$, we have $\rho(x^{(k)}; s^{(k)}) \geq \eta_2$ as noted above. Therefore,

$$\Delta^{(k+1)} = \gamma_2 \Delta^{(k)} > \Delta^{(k)} \geq \min\{\Delta^{(L)}, \gamma_1 \bar{\Delta}\}.$$

In the opposite case $\Delta^{(k)} > \bar{\Delta}$, the step might not have been successful and the trust-region radius might have been reduced, but we can estimate it as

$$\Delta^{(k+1)} \geq \gamma_1 \Delta^{(k)} > \gamma_1 \bar{\Delta} \geq \min\{\Delta^{(L)}, \gamma_1 \bar{\Delta}\}.$$

To summarize, we have shown (**) for $k + 1$ and the induction is complete.

We now have reached the contradiction that $\Delta^{(k)}$ is bounded away from zero for $k \geq L$ and simultaneously, the subsequence $\Delta^{(k)} \xrightarrow{k \in S} 0$; see above **Step (1)**.

Statement (2): Suppose now that f' is uniformly continuous on the set of iterates $\{x^{(k)} \mid k \in \mathbb{N}_0\}$, i. e., for every $\varepsilon > 0$, there exists $\delta > 0$ such that $\|x^{(k)} - x^{(\ell)}\|_M \leq \delta$ implies $\|f'(x^{(k)}) - f'(x^{(\ell)})\|_{M^{-1}} \leq \varepsilon$. We proceed again by contradiction and assume that (6.15) does *not* hold. That is, there exists $\varepsilon_2 > 0$ such that the index set

$$K_{2\varepsilon_2} := \{k \in \mathbb{N}_0 \mid \|f'(x^{(k)})\|_{M^{-1}} \geq 2\varepsilon_2\}$$

is infinite. The uniform continuity of f' implies the existence of $\delta > 0$ such that

$$\|f'(x^{(\ell)})\|_{M^{-1}} \geq \|f'(x^{(k)})\|_{M^{-1}} - \|f'(x^{(k)}) - f'(x^{(\ell)})\|_{M^{-1}} \geq \varepsilon_2 \quad (***)$$

holds for all $x^{(\ell)}$ with the property $\|x^{(\ell)} - x^{(k)}\|_M \leq \delta$ for some $k \in K_{2\varepsilon_2}$.

Consider now also the index set

$$K_{\varepsilon_2} := \{k \in \mathbb{N}_0 \mid \|f'(x^{(k)})\|_{M^{-1}} \geq \varepsilon_2\},$$

which is infinite as well due to $K_{2\varepsilon_2} \subseteq K_{\varepsilon_2}$. Recall that $S \subseteq \mathbb{N}_0$ denotes the index set of successful step proposals. The set $S \cap K_{\varepsilon_2}$ may be finite or infinite. In any case, [Lemma 6.8](#) implies

$$\sum_{k \in S \cap K_{\varepsilon_2}} \Delta^{(k)} < \infty.$$

Therefore, there exists $k_0 \in S \cap K_{\varepsilon_2}$ such that the remainder of this series (“Reihenrest”) that comes after k_0 is small. More precisely,

$$\sum_{\substack{j=k_0 \\ j \in S \cap K_{\varepsilon_2}}}^{\infty} \Delta^{(j)} < \delta. \quad (***)$$

In fact, by making k_0 larger, if necessary, k_0 can be chosen to lie in $k_0 \in K_{2\varepsilon_2}$. (**Quiz 6.3:** Why?)

We now show by induction that $\|x^{(\ell)} - x^{(k_0)}\|_M < \delta$ holds for all $\ell \geq k_0$. The claim holds trivially for $\ell = k_0$. As induction hypothesis, suppose that there exists $\ell \geq k_0$ such that $\|x^{(j)} - x^{(k_0)}\|_M < \delta$ is true for $j = k_0, \dots, \ell$. We can invoke [\(***\)](#) to see that $\|f'(x^{(j)})\|_{M^{-1}} \geq \varepsilon_2$ holds for all $j = k_0, \dots, \ell$. In other words, all indices $j = k_0, \dots, \ell$ belong to K_{ε_2} . We can therefore estimate

$$\begin{aligned} \|x^{(\ell+1)} - x^{(k_0)}\|_M &\leq \sum_{\substack{j=k_0 \\ j \in S}}^{\ell} \Delta^{(j)} && \text{unsuccessful steps do not move } x \\ &= \sum_{\substack{j=k_0 \\ j \in S \cap K_{\varepsilon_2}}}^{\ell} \Delta^{(j)} && \text{all indices } j = k_0, \dots, \ell \text{ belong to } K_{\varepsilon_2} \\ &\leq \sum_{\substack{j=k_0 \\ j \in S \cap K_{\varepsilon_2}}}^{\infty} \Delta^{(j)} && \text{summands are positive} \\ &< \delta && \text{by } (***). \end{aligned}$$

This concludes the induction step and we have shown that indeed $\|x^{(\ell)} - x^{(k_0)}\|_M < \delta$ holds for all $\ell \geq k_0$. Invoking again [\(***\)](#), we infer that $\|f'(x^{(\ell)})\|_{M^{-1}} \geq \varepsilon_2$ holds for all $\ell \geq k_0$, which is in contradiction to [\(6.14\)](#). \square

Remark 6.10 (on the [global convergence theorem 6.9](#)). *For the [global convergence theorem 6.9](#) to hold, it is not strictly necessary that the step proposal satisfy $\|s^{(k)}\|_M \leq \Delta^{(k)}$. A relaxed constraint of the form $\|s^{(k)}\|_M \leq \beta \Delta^{(k)}$ is enough and allows us to gain some more flexibility in a practical algorithm; see for instance [Ulbrich, Ulbrich, 2012](#), Satz 14.10 and eq.(14.50). However, in this class we are not going to exploit this algorithmically.*

§ 6.2 FAST LOCAL CONVERGENCE

In this section we show that the generic trust-region method [Algorithm 6.1](#) will transition to a local, inexact Newton method. This means that the trust-region constraint $\|s^{(k)}\|_M \leq \Delta^{(k)}$ will be inactive from a certain iteration index onwards. If one then solves the trust-region subproblems to sufficient accuracy (compare the forcing sequence in inexact Newton methods in § 5.6), one can obtain Q-superlinear or even Q-quadratic convergence of the iterates.

We restrict the discussion here to **trust region Newton methods**, which are defined by the choice $H^{(k)} = f''(x^{(k)})$. However, model Hessians based on quasi-Newton updates are very important in practice as well.⁴⁵

Theorem 6.11 (Transition to fast local convergence in [Algorithm 6.1](#)). *Suppose that f is of class C^2 and that the model Hessians $H^{(k)}$ in [Algorithm 6.1](#) are the exact Hessians $f''(x^{(k)})$. Assume that the sequence of objective values $f(x^{(k)})$ is bounded below by f . Moreover, suppose that the step proposals $s^{(k)}$ are feasible and satisfy the weak fraction of Cauchy decrease condition (6.12). Suppose further that the sublevel set $\mathcal{M}_f(x^{(0)}) := \{x \in \mathbb{R}^n \mid f(x) \leq f(x^{(0)})\}$ is compact.*

- (i) *Suppose that x^* is an accumulation point of $x^{(k)}$ and that $f''(x^*)$ is positive semidefinite. Then the entire sequence converges to x^* , i. e., x^* is indeed the unique limit point of $x^{(k)}$.*
- (ii) *There exists an index $k_0 \in \mathbb{N}$, such that*

(a) $\rho(x^{(k)}; s^{(k)}) > \eta_1$ holds for all $k \geq k_0$, i. e., the step proposal will be accepted.

(b) $f''(x^{(k)})$ is positive semidefinite and $\|f''(x^{(k)})^{-1} \nabla f(x^{(k)})\|_M \leq \frac{\Delta^{(k)}}{2}$ holds for all $k \geq k_0$.

- (iii) *If, in addition, the step proposals $s^{(k)}$ satisfy*

$$\|f''(x^{(k)}) s^{(k)} + \nabla f(x^{(k)})\|_{M^{-1}} \leq \eta^{(k)} \|\nabla f(x^{(k)})\|_{M^{-1}} \quad (6.16)$$

with a forcing sequence $\eta^{(k)} \searrow 0$, then $x^{(k)}$ converges to x^ Q-superlinearly w.r.t. the M -norm.*

Statement (b) means that from a certain index k_0 onwards, full exact Newton steps would be useful step proposals that are not only feasible w.r.t. the constraint $\|s^{(k)}\|_M \leq \Delta^{(k)}$ but lie well inside the trust region.

Condition (6.16) requires that the step proposal $s^{(k)}$ will eventually be close to the full exact Newton step in the sense that the relative residual norm is bounded by the forcing sequence $\eta^{(k)}$; compare the condition (5.36) for inexact Newton methods for root finding.

⁴⁵In contrast to the quasi-Newton line search methods from § 5.7, the positive definiteness of $H^{(k)}$ is no longer required. A further distinction is that one works with quasi-Newton update formulas for the model Hessian $H^{(k)}$ and not for the inverse $B^{(k)}$, since the inexact iterative solution of the trust-region subproblems (6.1) is based on matrix-vector products with $H^{(k)}$.

§ 6.3 SOLUTION OF THE TRUST-REGION SUBPROBLEM

We now address options for the inexact numerical solution of the trust-region subproblem (6.1), i. e., with a problem of the form

$$\begin{aligned} & \text{Minimize} && q(s) = f - b^\top s + \frac{1}{2} s^\top H s, \quad \text{where } s \in \mathbb{R}^n \\ & \text{subject to} && \|s\|_M \leq \Delta. \end{aligned} \tag{6.17}$$

The data of the problem are the model offset $q(0) = f \in \mathbb{R}$, (negative) model derivative $-q'(0) = b \in \mathbb{R}^n$, symmetric model Hessian $H \in \mathbb{R}^{n \times n}$ and trust-region radius $\Delta > 0$.

Although the Cauchy point is a sufficiently accurate solution of the trust-region subproblem in order to achieve global convergence (Theorem 6.9), and fast local convergence can only take effect as soon as the trust-region constraint $\|s\|_M \leq \Delta$ is inactive and no longer plays a role (Theorem 6.11), we will characterize the exact global solution(s) of (6.17) first.

Note: Due to the possibility of negative eigenvalues in H , problem (6.17) is not convex in general.

Theorem 6.12 (Characterization of global solutions of the trust-region subproblem (6.17)).

- (i) Suppose that $s \in \mathbb{R}^n$ is a global minimizer of (6.17). Then there exists $\mu \in \mathbb{R}$ such that the following holds:

$$\mu \geq 0, \quad \|s\|_M - \Delta \leq 0, \quad \mu (\|s\|_M - \Delta) = 0 \tag{6.18a}$$

$$(H + \mu M) s = b \tag{6.18b}$$

$$H + \mu M \text{ is positive semidefinite.} \tag{6.18c}$$

The number μ is uniquely determined.

- (ii) Now suppose that $(s, \mu) \in \mathbb{R}^n \times \mathbb{R}$ is such that (6.18) is satisfied. Then s is a global minimizer of (6.17).
- (iii) If $(s, \mu) \in \mathbb{R}^n \times \mathbb{R}$ is such that (6.18) is satisfied and in addition, $H + \mu M$ is positive definite, then s is the **unique** global minimizer of (6.17).

Proof. **Statement (i):** Suppose that s is a global minimizer of (6.17). Then $\|s\|_M \leq \Delta$ is obvious.

Case 1: $\|s\|_M < \Delta$ holds.

Then s is also a local minimizer of the unconstrained problem

$$\text{Minimize} \quad q(s), \quad \text{where } s \in \mathbb{R}^n.$$

Consequently, the necessary optimality condition of first order (Theorem 3.1) holds, i. e.,

$$\nabla q(s) = H s - b = 0,$$

as well as the necessary optimality condition of second order (Theorem 3.2), i. e., H is positive semidefinite. This shows that (6.18) holds for the choice $\mu = 0$.⁴⁶

Owing to the complementarity in (6.18a), $\mu = 0$ is the only possible choice.

Case 2: $\|s\|_M = \Delta$ holds, and in particular, $s \neq 0$.

We first show that there exists $\mu \geq 0$ such that $(H + \mu M)s = b$ holds. We proceed by contradiction and therefore suppose that for all $\mu \geq 0$, we have $(H + \mu M)s \neq b$.

The choice $\mu = 0$ implies $y := \nabla q(s) = Hs - b \neq 0$. The choices $\mu > 0$ imply that the vectors y and Ms cannot be anti-parallel. Therefore, $M^{-1}y$ and s cannot be anti-parallel either. Concerning the angle α (w.r.t. the M -inner product) between these two vectors, we thus have

$$\cos \alpha = \frac{(M^{-1}y)^\top Ms}{\|M^{-1}y\|_M \|s\|_M} = \frac{y^\top s}{\|y\|_{M^{-1}} \|s\|_M} > -1.$$

Let v be a vector in the direction of the angle bisector between $-M^{-1}y$ and $-s$, e. g.,

$$v := -\frac{M^{-1}y}{\|y\|_{M^{-1}}} - \frac{s}{\|s\|_M} \neq 0.$$

Then we have

$$\begin{aligned} y^\top v &= y^\top \left(-\frac{M^{-1}y}{\|y\|_{M^{-1}}} - \frac{s}{\|s\|_M} \right) \\ &= -\|y\|_{M^{-1}} - \frac{y^\top s}{\|s\|_M} \frac{\|y\|_{M^{-1}}}{\|y\|_{M^{-1}}} \\ &= -\|y\|_{M^{-1}} (1 + \cos \alpha) \\ &< 0. \end{aligned}$$

Hence we conclude $q'(s)v = y^\top v < 0$ and therefore v is a descent direction for q at s . Due to

$$\begin{aligned} \left[\frac{d}{dt} \frac{1}{2} \|s + tv\|_M^2 \right]_{t=0} &= v^\top Ms \\ &= \left(-\frac{M^{-1}y}{\|y\|_{M^{-1}}} - \frac{s}{\|s\|_M} \right)^\top Ms \\ &= -\frac{y^\top s}{\|y\|_{M^{-1}} \|s\|_M} - \|s\|_M \\ &= -\|s\|_M (\cos \alpha + 1) \\ &< 0 \end{aligned}$$

we have $\|s + tv\|_M < \|s\|_M = \Delta$ for small enough $t > 0$. Hence we can obtain a feasible point with a strictly smaller objective value than s , which is in contradiction to the optimality of s .

Consequently, it must be possible to satisfy the conditions (6.18a) and (6.18b) with some $\mu \geq 0$. It is not difficult to see that, in fact, μ must be unique. Indeed, the assumption $Hs + \mu_1 Ms = b = Hs + \mu_2 Ms$ leads to $(\mu_1 - \mu_2)Ms = 0$, which is only possible for $\mu_1 = \mu_2$ due to $s \neq 0$ and the invertibility of M .

⁴⁶In this case q is convex, and thus s is also a global minimizer of the unconstrained problem.

It remains to show that $H + \mu M$ is positive semidefinite, i. e., (6.18c). To this end, we consider a direction $d \in \mathbb{R}^n$ with the property $d^T M s < 0$. We need to show

$$d^T (H + \mu M) d \geq 0.$$

Let us define $t := \frac{-2 d^T M s}{\|d\|_M^2} > 0$. Then

$$\|s + t d\|_M^2 = \|s\|_M^2 + 2 t d^T M s + t^2 \|d\|_M^2 = \|s\|_M^2 \leq \Delta^2.$$

The global optimality of s implies

$$\begin{aligned} 0 &\leq q(s + t d) - q(s) \\ &= q'(s) (t d) + \frac{1}{2} (t d)^T H (t d) \\ &= t y^T d + \frac{t^2}{2} d^T H d \\ &= -t \mu s^T M d + \frac{t^2}{2} d^T H d \quad \text{due to } y = H s - b = -\mu M s \\ &= \frac{t^2}{2} \mu \|d\|_M^2 + \frac{t^2}{2} d^T H d \quad \text{due to } \frac{t}{2} \|d\|_M^2 = -d^T M s \\ &= \frac{t^2}{2} d^T (H + \mu M) d. \end{aligned}$$

Thus we have confirmed that $d^T (H + \mu M) d \geq 0$ holds for all directions $d \in \mathbb{R}^n$ satisfying $d^T M s < 0$. Since the sign of d is irrelevant, the same result likewise holds for directions $d^T M s > 0$. The remaining case of directions $d^T M s = 0$ follows by continuity.

Statement (ii): Suppose that $(s, \mu) \in \mathbb{R}^n \times \mathbb{R}$ is such that (6.18) is satisfied. Let $\bar{s} \in \mathbb{R}^n$ with $\|\bar{s}\|_M \leq \Delta$ be an arbitrary comparison point, $d := \bar{s} - s$ and $y := \nabla q(s) = H s - b$ as above. We estimate

$$\begin{aligned} q(\bar{s}) - q(s) &= y^T d + \frac{1}{2} d^T H d \\ &= -\mu s^T M d + \frac{1}{2} d^T H d \quad \text{due to } y = H s - b = -\mu M s \text{ by (6.18b)} \\ &\geq -\mu s^T M d - \frac{1}{2} \mu \|d\|_M^2 \quad \text{by (6.18c)} \\ &= -\frac{\mu}{2} (2 s^T M d + \|d\|_M^2) \\ &= -\frac{\mu}{2} (\|d + s\|_M^2 - \|s\|_M^2) \\ &= -\frac{\mu}{2} (\|\bar{s}\|_M^2 - \|s\|_M^2) \\ &\geq 0. \end{aligned}$$

The previous inequality requires a comment. It holds trivially in case $\mu = 0$. For $\mu > 0$, (6.18a) implies $\|s\|_M^2 = \Delta^2$, and by assumption we have $\|\bar{s}\|_M^2 \leq \Delta^2$. This shows the final inequality and thus the global optimality of s for (6.17).

Statement (iii): If $H + \mu M$ is even positive definite, then the estimate above can be sharpened for $\bar{s} \neq s$, i. e., $d \neq 0$:

$$\begin{aligned} q(\bar{s}) - q(s) &= -\mu s^\top M d + \frac{1}{2} d^\top H d \\ &> -\mu s^\top M d - \frac{1}{2} \mu \|d\|_M^2 \\ &= \dots \\ &= -\frac{\mu}{2} (\|\bar{s}\|_M^2 - \|s\|_M^2) \\ &\geq 0. \end{aligned}$$

This shows that s is even the unique global minimizer of (6.17). \square

Remark 6.13 (on the characterization of global minimizers).

- (i) The remarkable fact about [Theorem 6.12](#) is that the optimality condition (6.18) is simultaneously necessary and sufficient, even though problem (6.17) is generally non-convex.
- (ii) As an alternative to the proof in [Theorem 6.12](#) we might use an optimality condition of Karush-Kuhn-Tucker type (see [Chapter 2](#)) to prove that (6.18a) and (6.18b) are necessary conditions for any local minimizer and, in particular, for global minimizers of (6.17). In this way, we will see that the number μ can be viewed as the unique Lagrange multiplier pertaining to the constraint

$$\frac{1}{2} (\|s\|_M^2 - \Delta^2) \leq 0,$$

which is of course equivalent to $\|s\|_M \leq \Delta$. As we can see easily, the linear independence constraint qualification (LICQ) always holds.⁴⁷ Proceeding in this way, however, we will not find the condition (6.18c) that is — as we saw in the proof — characteristic for global minimizers of (6.17).

- (iii) It was proved in [Martínez, 1994](#) that (6.17) can have, besides its global minimizers, at most one additional local minimizer which is not a global minimizer.

Based on the characterization (6.18), one can devise methods to find an exact global minimizer of the trust-region subproblem (6.17). The most prominent method utilizes a one-dimensional Newton method for the equation

$$\frac{1}{\|(H + \mu M)^{-1}b\|_M} - \frac{1}{\Delta} = 0$$

to determine the value of μ , unless $\mu = 0$ and $s = H^{-1}b$ already solve (6.18); see [Nocedal, Wright, 2006](#), Chapter 4.3 for details if you are interested.

In the remainder of this section we discuss a practical method to find an inexact solution s to the trust-region subproblem (6.17). Our goal is to satisfy

⁴⁷See [Definition 8.16](#) for the definition of LICQ. In case $\|s\|_M < \Delta$, the only constraint present is inactive, so the LICQ holds. Otherwise we have $\|s\|_M = \Delta > 0$ and thus $s \neq 0$. This implies that the gradient of the only active constraint, $M s$, is non-zero and thus linearly independent, so the LICQ holds also in this case.

- (i) the conditions for global convergence imposed in [Theorem 6.9](#), i. e., the trust-region constraint $\|s\|_M \leq \Delta$ and the (weak) fraction of Cauchy decrease condition (6.11),
- (ii) the conditions for fast local convergence imposed in [Theorem 6.11](#).

It will turn out that a clever modification of the conjugate gradient method — the **Steihaug(-Toint) conjugate gradient method**⁴⁸ — is capable of satisfying these requirements.⁴⁹

This variant of the CG method will be applied to the linear system $HS = b$. In case that H is s. p. d., this system constitutes the necessary and sufficient optimality condition for an unconstrained trust-region subproblem, i. e., (6.17) with $\Delta = \infty$. The Steihaug-Toint variant of the CG algorithm has two significant modifications compared to the base version ([Algorithm 4.17](#)).⁵⁰

- (1) Similarly as in the truncated conjugate method ([Algorithm 5.41](#)), we start the method with $s^{(0)} = 0$ and we detect the occurrence of a search direction $p^{(\ell)}$ with **non-positive curvature** $(p^{(\ell)})^\top H p^{(\ell)} \leq 0$. In contrast to the truncated CG method, where we would stop immediately, we proceed with the current step and produce $s^{(\ell+1)} = s^{(\ell)} + \alpha^* p^{(\ell)}$, where α^* is not the usual Cauchy step size but is chosen such that $s^{(\ell+1)}$ lies on the boundary of the trust region. We then stop the method.
- (2) In case that the current step would **leave the trust region**, i. e., in case $\|s^{(\ell)} + \alpha^{(\ell)} p^{(\ell)}\|_M > \Delta$, we do not utilize the full step size $\alpha^{(\ell)}$ but, again, proceed only to the boundary of the trust region and then stop the algorithm.

If none of these two situations occur, then the Steihaug-Toint CG method stops as soon as an approximate solution to $HS = -b$ has been found with sufficiently small residual norm. With regards to [Theorem 6.11](#) we utilize the relative residual norm and a tolerance given by a suitable forcing sequence, compare (5.37),

$$\frac{\|\text{residual associated with } s^{(\ell)}\|_{M^{-1}}}{\|\text{residual associated with } 0\|_{M^{-1}}} = \frac{\|\zeta^{(\ell)}\|_{M^{-1}}}{\|b\|_{M^{-1}}} = \frac{\|H s^{(\ell)} - b\|_{M^{-1}}}{\|b\|_{M^{-1}}} \leq \eta. \quad (6.19)$$

In case the outer iterate $x^{(k)}$ is already close to a point x^* satisfying the second-order sufficient optimality condition, one can guarantee that the Steihaug-Toint CG method will *not* stop for any of the two reasons above but it stops as soon as (6.19) holds. Therefore, the condition (6.16) concerning the accuracy of the step proposal is satisfied, and [Theorem 6.11](#) yields the Q-superlinear convergence, provided that the further requisites of that theorem hold.

The Steihaug-Toint CG algorithm for the inexact solution of (6.17) is given in [Algorithm 6.14](#).

Algorithm 6.14 (Steihaug-Toint conjugate gradient method for the trust-region subproblem (6.17)).

Input: *negative model derivative* $-q'(0) = b \in \mathbb{R}^n$

⁴⁸after [Steihaug, 1983](#) and [Toint, 1981](#)

⁴⁹Other, slightly more elaborate approaches, can be found in the literature, e. g., the **dogleg method** and the **two-dimensional subspace minimization approach**; see [Nocedal, Wright, 2006](#), Chapter 4.1 if you are interested.

⁵⁰As we did with the truncated conjugate method ([Algorithm 5.41](#)) in the context of inexact Newton methods, we switch to problem adapted variable names. That is, we use iterates $s^{(\ell)}$, search directions $p^{(\ell)}$ and residuals $\zeta^{(\ell)}$.

Input: symmetric matrix H (or matrix-vector products with H)

Input: s. p. d. matrix M (or matrix-vector products with M^{-1})

Input: relative residual ε_{rel}

Input: trust-region radius $\Delta > 0$

Output: approximate solution of the trust-region subproblem (6.17)

```

1: Set  $\ell := 0$ 
2: Set  $s^{(0)} := 0$                                      // zero initial guess

25:  else
26:    Determine  $\alpha^*$  as the positive solution of  $\|s^{(\ell)} + \alpha p^{(\ell)}\|_M = \Delta$ 
27:    Set  $s^{(\ell+1)} := s^{(\ell)} + \alpha^* p^{(\ell)}$              // go to the boundary of the trust region
28:    Set  $\ell := \ell + 1$ 
29:    Abort the while loop
30:  end if
31: end while
32: return  $s^{(\ell)}$ 

```

Remark 6.15 (on Algorithm 6.14).

(i) The first iterate $s^{(1)}$ is the Cauchy point of problem (6.17).

(ii) We consider three cases which may occur in an iteration.

(a) In case of a “usual” CG step (identical to what the plain CG algorithm 4.17 would produce),

then

$$q(s^{(\ell+1)}) = q(s^{(\ell)}) - \frac{1}{2} \underbrace{\alpha^{(\ell)}}_{>0} \underbrace{\delta^{(\ell)}}_{>0}$$

holds, see (4.12).

- (b) If $\theta^{(\ell)} > 0$ holds (the current search direction $p^{(\ell)}$ is a direction of positive curvature) but the full Cauchy step $s^{(\ell)} + \alpha^{(\ell)} p^{(\ell)}$ lands outside the trust region, then it is useful follow the convex function

$$\alpha \mapsto \varphi(\alpha) := f + b^\top (s^{(\ell)} + \alpha p^{(\ell)}) + \frac{1}{2} (s^{(\ell)} + \alpha p^{(\ell)})^\top H (s^{(\ell)} + \alpha p^{(\ell)})$$

in the direction $\alpha > 0$ to the boundary of the trust region in order to obtain the largest possible descent, since

$$\varphi'(0) = b^\top p^{(\ell)} + (s^{(\ell)})^\top H p^{(\ell)} = (\zeta^{(\ell)})^\top p^{(\ell)} = -\delta_\ell = -\|\zeta^{(\ell)}\|_{M^{-1}}^2 < 0$$

ist.

- (c) If, by contrast, $\theta^{(\ell)} \leq 0$ holds (the current search direction $p^{(\ell)}$ is a direction of non-positive curvature), then the function φ is concave. This suggests, again, to proceed to the boundary of the trust region in the direction $\alpha > 0$.
- (iii) The considerations above show: in case the Steihaug-Toint CG algorithm does not stop with $s^{(1)}$ but continues, the further iterates continue to reduce the objective q monotonically. Therefore, the inexact solution $s^{(\ell)}$ returned by Algorithm 6.14 always satisfies the fraction of Cauchy decrease condition (6.11) with $\underline{C} = 1$.
- (iv) The reason for terminating the algorithm when an iterate $s^{(\ell+1)}$ is about to leave the trust region is the following. As we know from Lemma 4.22, the sequence of norms $\|s^{(\ell)} - 0\|_M$ is strictly monotonically increasing. If we would let the algorithm continue, we would never return into the trust region.
- (v) Concerning the recursive update of the quantity $\|s^{(\ell)}\|_M$ without using the matrix M , we can refer to (4.33)–(4.34) to obtain the formulas

$$\omega^{(0)} := 0, \quad \omega^{(k+1)} := \omega^{(k)} + 2\alpha^{(k)}\xi^{(k)} + (\alpha^{(k)})^2\gamma^{(k)} \quad (6.20a)$$

$$\xi^{(0)} := 0, \quad \xi^{(k+1)} := \beta^{(k+1)}(\xi^{(k)} + \alpha^{(k)}\gamma^{(k)}) \quad (6.20b)$$

$$\gamma^{(0)} := \delta^{(0)}, \quad \gamma^{(k+1)} := \delta^{(k+1)} + (\beta^{(k+1)})^2\gamma^{(k)} \quad (6.20c)$$

for the quantities

$$\omega^{(\ell)} := \|s^{(\ell)} - 0\|_M^2, \quad \xi^{(\ell)} := (s^{(\ell)} - 0)^\top M p^{(\ell)}, \quad \gamma^{(\ell)} := \|p^{(\ell)}\|_M^2.$$

- (vi) Using these quantities, we can evaluate the step size α^* required to reach the boundary by solving the quadratic equation

$$\|s^{(\ell)} + \alpha p^{(\ell)}\|_M^2 = \omega^{(\ell)} + \alpha \xi^{(\ell)} + \alpha^2 \gamma^{(\ell)} = \Delta^2.$$

Due to $\omega^{(\ell)} = \|s^{(\ell)}\|_M^2 < \Delta$, this equation has exactly one positive solution, which is

$$\alpha^* := -\frac{\xi^{(\ell)}}{2\gamma^{(\ell)}} + \frac{\xi^{(\ell)}}{2\gamma^{(\ell)}} \left(1 - 4\gamma^{(\ell)}(\omega^{(\ell)} - \Delta^2)\right)^{1/2}.$$

End of Week 7

Chapter 2 Theory for Constrained Optimization Problems

§ 7 INTRODUCTION

In this chapter we come back to the generic constrained nonlinear optimization problem (**nonlinear program** or **NLP**) with basic set \mathbb{R}^n from (1.1),

$$\left. \begin{array}{ll} \text{Minimize} & f(x) \quad \text{where } x \in \mathbb{R}^n \\ \text{subject to} & g_i(x) \leq 0 \quad \text{for } i = 1, \dots, n_{\text{ineq}} \\ & \text{and } h_j(x) = 0 \quad \text{for } j = 1, \dots, n_{\text{eq}}. \end{array} \right\} \quad (7.1)$$

We have finitely many (possibly zero) inequality constraints $g_i: \mathbb{R}^n \rightarrow \mathbb{R}$ and equality constraints $h_j: \mathbb{R}^n \rightarrow \mathbb{R}$, i. e., $n_{\text{ineq}}, n_{\text{eq}} \in \mathbb{N}_0$. The set

$$F := \{x \in \mathbb{R}^n \mid g_i(x) \leq 0 \text{ for all } i = 1, \dots, n_{\text{ineq}}, h_j(x) = 0 \text{ for all } j = 1, \dots, n_{\text{eq}}\} \quad (7.2)$$

associated with problem (7.1) is termed the **feasible set**. Any $x \in F$ is termed a **feasible point**.

Our goal is to derive optimality conditions for (7.1) which are verifiable numerically and which will serve as the basis for numerical algorithms.

Assumption 7.1. Throughout *Chapter 2* we are assuming that $f: \mathbb{R}^n \rightarrow \mathbb{R}$, $g_i: \mathbb{R}^n \rightarrow \mathbb{R}$ and $h_j: \mathbb{R}^n \rightarrow \mathbb{R}$ are all C^1 functions, $i = 1, \dots, n_{\text{ineq}}$ and $j = 1, \dots, n_{\text{eq}}$.

The derivation of a first-order optimality condition for problem (7.1) is significantly more complex than the derivation for the unconstrained problem (**UP**) achieved in [Theorem 3.1](#). Recall that the proof was based on considering curves $\gamma(t) = x^* + t d$ which run through the local minimizer x^* . Since problem (**UP**) was unconstrained, we were free to choose any direction d and we obtained $f'(x^*) d = 0$ for all $d \in \mathbb{R}^n$. In the present situation, however, $\gamma(t)$ may not be feasible even for arbitrarily small $t > 0$. Therefore, we will need to restrict the directions d .

It will turn out that the appropriate set of directions is the tangent cone.

§ 7.1 THE TANGENT CONE

Definition 7.2 (Tangent cone). Suppose that $M \subseteq \mathbb{R}^n$ is an arbitrary set and $x \in M$. Then

$$\mathcal{T}_M(x) := \left\{ d \in \mathbb{R}^n \mid \text{there exist sequences } x^{(k)} \in M \text{ and } t^{(k)} \searrow 0 \text{ such that } d = \lim_{k \rightarrow \infty} \frac{x^{(k)} - x}{t^{(k)}} \right\} \quad (7.3)$$

is termed the **tangent cone** of M at x . A vector $d \in \mathcal{T}_M(x)$ is termed a **tangent direction** of M at x . We also define $\mathcal{T}_M(x) := \emptyset$ for $x \notin M$.

Note: The sequence $x^{(k)}$ in (7.3) necessarily converges to x .

The tangent cone is also known as **contingent cone** or **Bouligand cone** in the literature. By the way, a set $K \subseteq \mathbb{R}^n$ is termed a **cone** if $x \in K$ and $\beta > 0$ imply that $\beta x \in K$ holds.

Lemma 7.3 (Properties of the tangent cone). Suppose that $M \subseteq \mathbb{R}^n$ is an arbitrary set. Then $\mathcal{T}_M(x)$ is a closed cone.

Proof. We can assume $x \in M$ since otherwise $\mathcal{T}_M(x) = \emptyset$ holds, which is a closed cone.

We first show the cone property. Suppose that $d \in \mathcal{T}_M(x)$ and $\beta > 0$. That is, there exist sequences $x^{(k)} \in M$ and $t^{(k)} \searrow 0$ such that $d = \lim_{k \rightarrow \infty} \frac{x^{(k)} - x}{t^{(k)}}$. Replacing $t^{(k)}$ by $\beta^{-1}t^{(k)}$, the limit becomes βd . This shows $\beta d \in \mathcal{T}_M(x)$.

It remains to show the closeness of $\mathcal{T}_M(x)$. To this end, let $d^{(\ell)} \in \mathcal{T}_M(x)$ be a sequence which converges to some $d \in \mathbb{R}^n$. We need to show $d \in \mathcal{T}_M(x)$.

For each $\ell \in \mathbb{N}$, there exist sequences $(x^{(\ell,k)})_k \in M$ and $(t^{(\ell,k)})_k$ satisfying

$$x^{(\ell,k)} \rightarrow x, \quad t^{(\ell,k)} \searrow 0 \quad \text{and} \quad \frac{x^{(\ell,k)} - x}{t^{(\ell,k)}} \rightarrow d^{(\ell)} \quad \text{as } k \rightarrow \infty.$$

This implies that for each $\ell \in \mathbb{N}$, there exists an index $k^{(\ell)}$ such that

$$\|x^{(k^{(\ell)})} - x\| \leq \frac{1}{\ell}, \quad 0 < t^{(k^{(\ell)})} \leq \frac{1}{\ell} \quad \text{and} \quad \left\| \frac{x^{(k^{(\ell)})} - x}{t^{(k^{(\ell)})}} - d^{(\ell)} \right\| \leq \frac{1}{\ell}.$$

We now consider the “diagonal” sequences

$$\widehat{x}^{(\ell)} := x^{(k^{(\ell)})} \quad \text{and} \quad \widehat{t}^{(\ell)} := t^{(k^{(\ell)})}.$$

These satisfy $\widehat{x}^{(\ell)} \rightarrow x$ and $\widehat{t}^{(\ell)} \searrow 0$ as well as

$$\left\| \frac{\widehat{x}^{(\ell)} - x}{\widehat{t}^{(\ell)}} - d \right\| \leq \left\| \frac{\widehat{x}^{(\ell)} - x}{\widehat{t}^{(\ell)}} - d^{(\ell)} \right\| + \|d^{(\ell)} - d\| \leq \frac{1}{\ell} + \|d^{(\ell)} - d\| \rightarrow 0,$$

which shows that d belongs to $\mathcal{T}_M(x)$. □

We can now formulate and prove a first version of the first-order necessary optimality condition for local minimizers of (7.1).

Theorem 7.4 (First-order necessary optimality condition).

Suppose that x^* is a local minimizer of (7.1). Then

$$f'(x^*) d \geq 0 \quad \text{for all } d \in \mathcal{T}_F(x^*). \quad (7.4)$$

This theorem states that in a local minimizer, f is growing to first order in any direction tangent to the feasible set.

Proof. Suppose that $d \in \mathcal{T}_F(x^*)$. Then there exist sequences $x^{(k)} \in F$ and $t^{(k)} \searrow 0$ such that

$$d = \lim_{k \rightarrow \infty} \frac{x^{(k)} - x^*}{t^{(k)}}$$

holds. Since f is continuously differentiable, the [mean value theorem 2.4](#) implies that there exist numbers $\xi^{(k)} \in (0, 1)$ such that

$$f(x^{(k)}) = f(x^*) + f'(x^* + \xi^{(k)}(x^{(k)} - x^*))(x^{(k)} - x^*).$$

Using the local optimality of x^* and the fact that $x^{(k)} \rightarrow x^*$, we obtain

$$\begin{aligned} 0 &\leq f(x^{(k)}) - f(x^*) \\ &= f'(x^* + \xi^{(k)}(x^{(k)} - x^*))(x^{(k)} - x^*). \end{aligned}$$

Division by $t^{(k)}$ leaves us with

$$0 \leq \underbrace{f'(x^* + \xi^{(k)}(x^{(k)} - x^*))}_{\rightarrow x^*} \underbrace{\left(\frac{x^{(k)} - x^*}{t^{(k)}}\right)}_{\rightarrow d}.$$

Using again the C^1 -property of f , we infer that the expression on the right converges, so we conclude

$$0 \leq f'(x^*) d. \quad \square$$

In analogy to § 3, we refer to points $x \in F$ satisfying (7.4) as **stationary points**.

There are two obstacles that make the first-order necessary optimality condition (7.4) generally difficult to use in practice:

- (1) (7.4) comes in the form of a variational inequality. Even when a candidate point x^* is given, it may be difficult to verify (7.4) due to the generally infinite number of tangent directions $d \in \mathcal{T}_F(x^*)$. Finding a candidate point x^* on the basis of (7.4) is even more difficult.

- (2) The tangent cone's implicit definition can render its explicit characterization difficult. After all, $\mathcal{T}_F(x)$ only refers to the feasible set F itself but it does not depend on the **description** (7.2) of F in terms of the inequality and equality constraints g_i and h_j .

Therefore we now seek to replace the tangent cone $\mathcal{T}_F(x)$ by a cone which is simpler to handle algorithmically. More precisely, we will try and replace an analytical/geometrical object (the tangent cone) by an algebraic object (the linearizing cone).

§ 7.2 THE LINEARIZING CONE

Definition 7.5 (Linearizing cone).

Consider the feasible set F as in (7.2).

- (i) For $x \in F$, we define

$$\begin{aligned}\mathcal{A}(x) &:= \{i \in \{1, \dots, n_{\text{ineq}}\} \mid g_i(x) = 0\} && \text{the set of active indices at } x, \\ \mathcal{I}(x) &:= \{i \in \{1, \dots, n_{\text{ineq}}\} \mid g_i(x) < 0\} && \text{the set of inactive indices at } x.\end{aligned}$$

- (ii) For $x \in F$, the set

$$\mathcal{T}_F^{\text{lin}}(x) := \left\{ d \in \mathbb{R}^n \left| \begin{array}{ll} g'_i(x) d \leq 0 & \text{for all } i \in \mathcal{A}(x) \\ h'_j(x) d = 0 & \text{for all } j = 1, \dots, n_{\text{eq}} \end{array} \right. \right\} \quad (7.5)$$

is termed the **linearizing cone** or **cone of first-order feasible directions** to the feasible set at x . We set $\mathcal{T}_F^{\text{lin}}(x) := \emptyset$ when $x \notin F$.

Note: Inactive inequalities do not play a role in the definition of the linearizing cone.

Remark 7.6 (on the linearizing cone).

- (i) Consider the convex polyhedral set¹

$$F^{\text{lin}}(x) = \left\{ y \in \mathbb{R}^n \left| \begin{array}{ll} g_i(x) + g'_i(x)(y - x) \leq 0 & \text{for all } i = 1, \dots, n_{\text{ineq}} \\ h_j(x) + h'_j(x)(y - x) = 0 & \text{for all } j = 1, \dots, n_{\text{eq}} \end{array} \right. \right\}$$

for a given point $x \in F$. One can show that the linearizing cone is also the tangent cone to $F^{\text{lin}}(x)$ at the point $x \in F \cap F^{\text{lin}}(x)$, i. e.,

$$\mathcal{T}_F^{\text{lin}}(x) = \mathcal{T}_{F^{\text{lin}}(x)}(x).$$

- (ii) $\mathcal{T}_F^{\text{lin}}(x)$ is a closed convex cone.

- (iii) In contrast to the tangent cone $\mathcal{T}_F(x)$, the linearizing cone $\mathcal{T}_F^{\text{lin}}(x)$ does depend on the **description** of the feasible set F in terms of the inequality and equality constraints.

¹A convex polyhedral set is the intersection of finitely many half spaces.

Lemma 7.7 (Relation between the cones).

Consider the feasible set F as in (7.2) and $x \in F$. Then $\mathcal{T}_F^{\text{lin}}(x) \subseteq \mathcal{T}_F(x)$.

Proof. Suppose that $d \in \mathcal{T}_F(x)$. Then there exist sequences $x^{(k)} \in F$ and $t^{(k)} \searrow 0$ such that

$$d = \lim_{k \rightarrow \infty} \frac{x^{(k)} - x}{t^{(k)}}.$$

We prove that $g'_i(x) d \leq 0$ holds for all $i \in \mathcal{A}(x)$. Let us fix $i \in \mathcal{A}(x)$. The [mean value theorem 2.4](#) implies

$$\begin{aligned} 0 &\geq g_i(x^{(k)}) \quad \text{since } x^{(k)} \text{ is feasible} \\ &= \underbrace{g_i(x)}_{=0} + g'_i(x + \xi^{(k)}(x^{(k)} - x))(x^{(k)} - x) \end{aligned}$$

with some $\xi^{(k)} \in (0, 1)$. Division by $t^{(k)}$ and passage to the limit $k \rightarrow \infty$ yields $0 \geq g'_i(x) d$.

Analogously we can show $h'_j(x) d = 0$ for all $j = 1, \dots, n_{\text{eq}}$, and thus we obtain $d \in \mathcal{T}_F^{\text{lin}}(x)$. \square

§ 7.3 POLAR CONES

The formulation of optimality conditions in an algebraic form amenable to solution algorithms is going to require the introduction of a [dual description](#) of the linearizing cone $\mathcal{T}_F^{\text{lin}}(x)$. We now introduce such a dual description for arbitrary sets.

Definition 7.8 (Polar cone). Suppose that $M \subseteq \mathbb{R}^n$ is an arbitrary set. The [polar cone](#) to M is defined as

$$M^\circ := \{s \in \mathbb{R}^n \mid s^\top x \leq 0 \text{ for all } x \in M\}. \quad (7.6)$$

Note: The polar cone consists of the normal vectors $s \in \mathbb{R}^n$ of hyperplanes through the origin such that M is entirely contained in the negative half space $H^-(s, 0) = \{y \in \mathbb{R}^n \mid s^\top y \leq 0\}$. One also says that the hyperplane $s^\top y = 0$ [separates](#) 0 and M .

Lemma 7.9 (Properties of the polar cone). Suppose that $M, M_1, M_2 \subseteq \mathbb{R}^n$ are arbitrary sets.

- (i) M° is a closed convex cone.
- (ii) $M_1 \subseteq M_2$ implies $M_2^\circ \subseteq M_1^\circ$.

Proof. \square

Example 7.10 (Polar cones).

Figure 7.1: Illustration of two sets M which have the same polar cone M° .

- (i) Suppose that A is an affine subspace of \mathbb{R}^n , i. e., $A = U + \{\bar{x}\}$ where U is a subspace of \mathbb{R}^n and $\bar{x} \in \mathbb{R}^n$. Then $A^\circ = U^\perp$ (the orthogonal complement of U w.r.t. the Euclidean inner product).
- (ii) In the absence of inequality constraints ($n_{\text{ineq}} = 0$), the polar of the linearizing cone has the representation

$$\begin{aligned}\mathcal{T}_F^{\text{lin}}(x)^\circ &= \{s \in \mathbb{R}^n \mid s \text{ is some linear combination of } h'_j(x)^\top, j = 1, \dots, n_{\text{eq}}\} \\ &= \text{range } h'(x)^\top\end{aligned}$$

for $x \in F$.

- (iii) Let $N := (\mathbb{R}_{\geq 0})^n$ denote the non-negative orthant in \mathbb{R}^n . Then $N^\circ = (\mathbb{R}_{\leq 0})^n$ is the non-positive orthant.

§ 7.4 THE FARKAS LEMMA AND THE REPRESENTATION OF $\mathcal{T}_F^{\text{lin}}(x)^\circ$

We recall that our plan is to understand the dual description $\mathcal{T}_F^{\text{lin}}(x)^\circ$ of the linearizing cone $\mathcal{T}_F^{\text{lin}}(x)$. In the absence of inequality constraints, this polar has already been characterized in [Statement \(ii\)](#) of [Example 7.10](#). For the general case, we require the Farkas lemma.

Lemma 7.11 (Farkas lemma (1902)).

Suppose that $B \in \mathbb{R}^{m \times n}$ and $c \in \mathbb{R}^m$. Then the following are equivalent.

- (i) The linear system $B^\top \xi = c$ has a non-negative solution $\xi \geq 0$.

(ii) All elements of $\{d \in \mathbb{R}^n \mid Bd \geq 0\}$ satisfy $c^\top d \geq 0$.

Statement (i) means that c belongs to the closed convex cone²

$$K := \{B^\top \xi \mid \xi \in \mathbb{R}^m, \xi \geq 0\}.$$

In order to understand Statement (ii), we reason as follows:

$$\begin{aligned} Bd \geq 0 &\Leftrightarrow \xi^\top Bd \geq 0 \quad \text{for all } \xi \geq 0 \quad (\text{by Statement (iii) of Example 7.10}) \\ &\Leftrightarrow d^\top (B^\top \xi) \geq 0 \quad \text{for all } \xi \geq 0 \\ &\Leftrightarrow K \text{ is a subset of the half space } H^+(d, 0) = \{x \in \mathbb{R}^n \mid d^\top x \geq 0\}. \end{aligned}$$

We can thus read Statement (ii) as follows. Any half space $H^+(d, 0)$ that contains the cone K also contains the point c . Therefore, the negation of Statement (ii) means that there exists a vector d such that K is contained in $H^+(d, 0)$ but the point c is not. In this case, we say that the hyperplane $H(d, 0)$ **separates** K and c .

Figure 7.2: Illustration of both cases in the Farkas lemma 7.11. Left: Statements (i) and (ii) are both true. Right: Statements (i) and (ii) are both false.

Proof of Lemma 7.11. We first show Statement (i) \Rightarrow Statement (ii): Suppose that $\xi \geq 0$ satisfies $B^\top \xi = c$. Moreover, let $d \in \mathbb{R}^n$ be such that $Bd \geq 0$. Then we obtain

$$c^\top d = (B^\top \xi)^\top d = \xi^\top (Bd) \geq 0.$$

In order to prove Statement (ii) \Rightarrow Statement (i), we consider the contraposition, i. e., \neg Statement (i) $\Rightarrow \neg$ Statement (ii). Thus we assume $c \notin K$. Due to $0 \in K$ we must have $c \neq 0$. Let $\text{cl } B_R(c)$ be the closed ball with radius $R = \|c\|$. We consider the orthogonal projection of c onto $K \cap \text{cl } B_R(c)$, i. e.,

$$\begin{aligned} &\text{Minimize} \quad \|x - c\|, \quad \text{where } x \in \mathbb{R}^n \\ &\text{subject to} \quad x \in K \cap \text{cl } B_R(c). \end{aligned} \tag{*}$$

Since K is closed and $\text{cl } B_R(c)$ is compact, $K \cap \text{cl } B_R(c)$ is compact as well. By the Weierstraß' extreme value theorem³, problem (*) has a global minimizer w . The point w is also a global minimizer of the relaxed problem

$$\begin{aligned} &\text{Minimize} \quad \|x - c\|, \quad \text{where } x \in \mathbb{R}^n \\ &\text{subject to} \quad x \in K, \end{aligned} \tag{**}$$

²It is very easy to check that K is a convex cone. We do not prove here that it is closed. Please see Lemma 6.10 if you are interested in the proof.

Herzog, 2022,

³A continuous function attains its global minimum (and its global maximum) on any compact set.

since points outside of $\text{cl } B_R(c)$ are definitely not global minimizers of (**). (**Quiz 7.1:** Why is it that points outside of $\text{cl } B_R(c)$ cannot be global minimizers of (**)?)

We now prove that $d = w - c$ serves as the normal vector of a hyperplane which separates K from the point c . The construction is illustrated in Figure 7.3. Notice that we have $d \neq 0$ due to $K \ni w \neq c \notin K$.

Suppose that y is an arbitrary point in K . All points on the line segment between y and w , i. e., $\alpha y + (1 - \alpha) w$ for $\alpha \in [0, 1]$, also belong to K due to convexity. We obtain

$$\begin{aligned} \|w - c\|^2 &\leq \|\alpha y + (1 - \alpha) w - c\|^2 \quad \text{since } w \text{ is optimal for (**)} \\ &= \|\alpha (y - w) + (w - c)\|^2 \\ &= \alpha^2 \|y - w\|^2 + 2\alpha (y - w)^\top (w - c) + \|w - c\|^2. \end{aligned}$$

This implies

$$2(y - w)^\top \underbrace{(w - c)}_{=d} \geq -\alpha \|y - w\|^2$$

for all $\alpha \in [0, 1]$. Passage to the limit $\alpha \searrow 0$ implies

$$(y - w)^\top d \geq 0 \text{ for all } y \in K. \quad (***)$$

Inserting $y = 2w$ and $y = 0$ (both belong to K), we conclude $w^\top d \geq 0$ and simultaneously $w^\top d \leq 0$, hence

$$w^\top d = 0. \quad (****)$$

Moreover,

$$c^\top d = (c - w)^\top d + w^\top d = -\underbrace{\|w - c\|^2}_{=d \neq 0} + \underbrace{w^\top d}_{=0} < 0. \quad (*****)$$

Overall we obtain

$$\begin{aligned} y^\top d &\geq w^\top d \quad \text{by (***)} \\ &= 0 \quad \text{by (****)} \\ &> c^\top d \quad \text{by (*****)} \end{aligned}$$

for all $y \in K$. This shows that $K \subseteq H^+(d, 0)$ but $c \notin H^+(d, 0)$. In other words, we obtain that indeed, $d = w - c$ serves as the normal vector of a hyperplane which separates K from the point c . That is, Statement (ii) does not hold, which was to be proved. \square

Remark 7.12. Statement (i) of the Farkas-Lemmas 7.11 can be verified numerically by checking whether or not the linear optimization problem

$$\begin{aligned} &\text{Minimize} \quad 0^\top \xi, \quad \text{where } \xi \in \mathbb{R}^m \\ &\text{subject to} \quad B^\top \xi = b \\ &\quad \text{and} \quad \xi \geq 0 \end{aligned}$$

has a feasible point, e. g., using phase I of the simplex method; see for instance Herzog, 2022, § 7.2.

Figure 7.3: Illustration of the construction of the normal vector $d = w - c$ of the separating hyperplane (red) in the proof of the Farkas-Lemmas 7.11.

Lemma 7.13 (Representation of $\mathcal{T}_F^{\text{lin}}(x)^\circ$).

Consider the feasible set F as in (7.2) and $x \in F$. Then the polar $\mathcal{T}_F^{\text{lin}}(x)^\circ$ of the linearizing cone has the representation

$$\begin{aligned} \mathcal{T}_F^{\text{lin}}(x)^\circ &= \left\{ \sum_{i \in \mathcal{A}(x)} \mu_i \nabla g_i(x) + \sum_{j=1}^{n_{\text{eq}}} \lambda_j \nabla h_j(x) \left| \begin{array}{ll} \mu_i \geq 0 & \text{for } i \in \mathcal{A}(x) \\ \lambda_j \in \mathbb{R} & \text{for } j = 1, \dots, n_{\text{eq}} \end{array} \right. \right\} \\ &= \left\{ \sum_{i=1}^{n_{\text{ineq}}} \mu_i \nabla g_i(x) + \sum_{j=1}^{n_{\text{eq}}} \lambda_j \nabla h_j(x) \left| \begin{array}{ll} \mu_i \geq 0 & \text{for } i = 1, \dots, n_{\text{ineq}} \\ \mu_i = 0 & \text{for } i \in \mathcal{I}(x) \\ \lambda_j \in \mathbb{R} & \text{for } j = 1, \dots, n_{\text{eq}} \end{array} \right. \right\}. \end{aligned} \quad (7.7)$$

Proof. We first show that the set on the right-hand side is a subset of $\mathcal{T}_F^{\text{lin}}(x)^\circ$. To this end, let y be a vector from the right-hand side of (7.7) and let $d \in \mathcal{T}_F^{\text{lin}}(x)$ be arbitrary, i. e., we have $g'_i(x) d \leq 0$ for all $i \in \mathcal{A}(x)$ and $h'_j(x) d = 0$ for all $j = 1, \dots, n_{\text{eq}}$. We need to show $y^\top d \leq 0$. This follows immediately from

$$\begin{aligned} y^\top d &= \sum_{i \in \mathcal{A}(x)} \underbrace{\mu_i}_{\geq 0} \underbrace{g'_i(x) d}_{\leq 0} + \sum_{j=1}^{n_{\text{eq}}} \lambda_j \underbrace{h'_j(x) d}_{=0} \\ &\leq 0 + 0. \end{aligned}$$

It remains to show that, conversely, $\mathcal{T}_F^{\text{lin}}(x)^\circ$ is also a subset of the set on the right-hand side. Here we will use the Farkas lemma 7.11 and set

$$B := \begin{bmatrix} -g'_i(x) |_{i \in \mathcal{A}(x)} \\ -h'_j(x) |_{j=1, \dots, n_{\text{eq}}} \\ h'_j(x) |_{j=1, \dots, n_{\text{eq}}} \end{bmatrix}.$$

This choice implies

$$d \in \mathcal{T}_F^{\text{lin}}(x) \iff B d \geq 0.$$

Now let $y \in \mathcal{T}_F^{\text{lin}}(x)^\circ$, hence

$$y^\top d \leq 0 \quad \text{for all } d \in \mathbb{R}^n \text{ satisfying } B d \geq 0.$$

We need to show that y has a representation as the elements in the right-hand side of (7.7). Using the Farkas lemma 7.11 with $b = -y$ yields that the system

$$B^\top \xi = -y \quad \text{has a solution } \xi \geq 0.$$

We split ξ according to

$$\xi =: \begin{pmatrix} \mu_i |_{i \in \mathcal{A}(x)} \\ \lambda_j^+ |_{j=1, \dots, n_{\text{eq}}} \\ \lambda_j^- |_{j=1, \dots, n_{\text{eq}}} \end{pmatrix} \quad \text{and set} \quad \lambda := \lambda^+ - \lambda^-.$$

Hence we can write $B^\top \xi = -y$ or $-B^\top \xi = y$ as

$$\sum_{i \in \mathcal{A}(x)} \mu_i \nabla g_i(x) + \sum_{j=1}^{n_{\text{eq}}} \lambda_j \nabla h_j(x) = y,$$

which confirms that y has indeed a representation as in (7.7). \square

§ 8 FIRST-ORDER NECESSARY OPTIMALITY CONDITIONS

We are now in the position to revisit first-order optimality conditions for (7.1). We already know from Theorem 7.4 that we have

$$f'(x^*) d \geq 0 \quad \text{for all } d \in \mathcal{T}_F(x^*) \quad (7.4)$$

at a local minimizer x^* . Equivalently, we could write

$$-\nabla f(x^*) \in \mathcal{T}_F(x^*)^\circ. \quad (8.1)$$

However, the tangent cone $\mathcal{T}_F(x^*)$ and its polar $\mathcal{T}_F(x^*)^\circ$ are generally difficult to characterize. By contrast, the linearizing cone $\mathcal{T}_F^{\text{lin}}(x^*)$ and its polar $\mathcal{T}_F^{\text{lin}}(x^*)^\circ$ have an explicit description in terms of the constraint functions' derivatives and are much easier to handle.

We have the relation $\mathcal{T}_F^{\text{lin}}(x) \subseteq \mathcal{T}_F(x)$ and thus, by Lemma 7.9, $\mathcal{T}_F(x)^\circ \subseteq \mathcal{T}_F^{\text{lin}}(x)^\circ$. This means that, unfortunately, $\mathcal{T}_F(x)^\circ$ may be “too small” and we **cannot expect**, in general,

$$-\nabla f(x^*) \in \mathcal{T}_F^{\text{lin}}(x^*)^\circ. \quad (8.2)$$

Before we address this gap and how to overcome it, let us see what (8.2) means explicitly.

Definition 8.1 (Lagrange function). *The function*

$$\begin{aligned} \mathcal{L}(x, \mu, \lambda) &:= f(x) + \sum_{i=1}^{n_{\text{ineq}}} \mu_i g_i(x) + \sum_{j=1}^{n_{\text{eq}}} \lambda_j h_j(x) \\ &= f(x) + \mu^\top g(x) + \lambda^\top h(x) \end{aligned} \quad (8.3)$$

is termed the **Lagrange function** or **Lagrangian** associated with problem (7.1).

One says that the constraints g and h are **adjoined** to the objective f .

Definition 8.2 (KKT conditions, Lagrange multipliers).

(i) The conditions

$$\nabla_x \mathcal{L}(x, \mu, \lambda) = \begin{cases} \nabla f(x) + \sum_{i=1}^{n_{\text{ineq}}} \mu_i \nabla g_i(x) + \sum_{j=1}^{n_{\text{eq}}} \lambda_j \nabla h_j(x) \\ \nabla f(x) + g'(x)^\top \mu + h'(x)^\top \lambda \end{cases} = 0, \quad (8.4a)$$

$$h(x) = 0, \quad (8.4b)$$

$$\mu \geq 0, \quad g(x) \leq 0, \quad \mu^\top g(x) = 0 \quad (8.4c)$$

are termed the **Karush-Kuhn-Tucker conditions** or **KKT conditions**⁴ associated with problem (7.1).

(ii) Given a point $x \in F$, any vectors μ and λ satisfying (8.4) are called **Lagrange multipliers** associated with the inequality and equality constraints, respectively, at x .

(iii) We denote the set of all Lagrange multipliers at $x \in F$ by

$$\Lambda(x) := \left\{ (\mu, \lambda) \left| \begin{array}{l} g'(x)^\top \mu + h'(x)^\top \lambda = -\nabla f(x) \\ \mu \geq 0, \quad \mu^\top g(x) = 0 \end{array} \right. \right\}. \quad (8.5)$$

We set $\Lambda(x) := \emptyset$ for $x \notin F$.

(iv) A point x is called a **KKT point** for problem (7.1) if $\Lambda(x) \neq \emptyset$, i. e., if there exist Lagrange multipliers (μ, λ) such that (x, μ, λ) satisfy the KKT conditions (8.4).

Remark 8.3 (on the KKT conditions).

(i) Condition (8.4c) is known as a **complementarity condition**.⁵ It can be written equivalently as

$$\mu_i \geq 0, \quad g_i(x) \leq 0, \quad \mu_i g_i(x) = 0 \quad \text{for all } i = 1, \dots, n_{\text{ineq}},$$

i. e., for every i , at least one of the two numbers μ_i and $g_i(x)$ is equal to 0. (This explains the name **complementarity**.)

In particular, a Lagrange multiplier μ_i associated with an inactive inequality constraint $g_i(x) < 0$ must be equal to 0. Sometimes, one writes (8.4c) in the form

$$0 \leq \mu \perp g(x) \leq 0.$$

(ii) Given $x \in F$, the conditions (8.5) on the Lagrange multipliers are linear equations and inequalities. Therefore, the set $\Lambda(x)$ is a polyhedron. Whether or not $\Lambda(x)$ is empty can be verified numerically by checking whether or not the linear optimization problem

$$\begin{aligned} & \text{Minimize} && 0^\top \mu + 0^\top \lambda \\ & \text{subject to} && g'(x)^\top \mu + h'(x)^\top \lambda = -\nabla f(x) \\ & && \text{and } \mu \geq 0 \\ & && \text{and } \mu^\top g(x) = 0 \end{aligned} \quad (8.6)$$

⁴Karush, 1939; Kuhn, Tucker, 1951

⁵A complementarity system is any system of inequalities and equalities in the form $a \geq 0$, $b \geq 0$ and $a^\top b = 0$.

has a feasible point, e. g., using phase I of the simplex method; see for instance [Herzog, 2022](#), § 7.2. The associated dual problem reads

$$\begin{aligned} & \text{Minimize} && f'(x) d, \quad \text{where } d \in \mathbb{R}^n \\ & \text{subject to} && g'_i(x) d \leq 0 \quad \text{for } i \in \mathcal{A}(x) \\ & && \text{and } h'_j(x) d = 0 \quad \text{for } j = 1, \dots, n_{\text{eq}}. \end{aligned} \tag{8.7}$$

That is, the dual problem considers the minimization of the linearized objective on the linearizing cone $\mathcal{T}_F^{\text{lin}}(x)$.

The primal problem (8.6) cannot be unbounded. The dual problem (8.7) always has the feasible point $d = 0$. Therefore, only the following two situations can occur:

- (1) Both problems (8.6) and (8.7) are solvable.
This means that Lagrange multipliers exist, i. e., $\Lambda(x) \neq \emptyset$.
- (2) The primal problem (8.6) is infeasible, and the dual problem (8.7) is unbounded.
No Lagrange multipliers exist, i. e., $\Lambda(x) = \emptyset$.

Situation (2) means that there exists a descent direction for the objective f at x , which belongs to the linearizing cone. By contrast, in *situation (1)*, all directions in the linearizing cone as non-descent directions.

We will now see that the KKT conditions are just an explicit way of writing (8.2).

Lemma 8.4 (Significance of the KKT conditions).

Consider the optimization problem (7.1). The following statements are equivalent.

- (i) x is a KKT point.
That is, there exist Lagrange multipliers (μ, λ) such that the KKT conditions (8.4) hold.
- (ii) x is a feasible point that satisfies (8.2).
That is, $-\nabla f(x) \in \mathcal{T}_F^{\text{lin}}(x)^\circ$.

Proof. Equation (8.4a) of the KKT conditions state that

$$-\nabla f(x) = \sum_{i=1}^{n_{\text{ineq}}} \mu_i \nabla g_i(x) + \sum_{j=1}^{n_{\text{eq}}} \lambda_j \nabla h_j(x) \tag{*}$$

holds with scalars λ_j and μ_i , for which (8.4c) implies: $\mu_i \geq 0$ for all $i = 1, \dots, n_{\text{ineq}}$ and even $\mu_i = 0$ for $i \in \mathcal{I}(x)$. Owing to the representation (7.7) of the polar $\mathcal{T}_F^{\text{lin}}(x)^\circ$ of the linearizing cone, (*) together with the conditions on μ is equivalent to $-\nabla f(x) \in \mathcal{T}_F^{\text{lin}}(x)^\circ$. Moreover, the conditions (8.4b) and (8.4c) ensure the feasibility of x . \square

The KKT conditions (8.4) associate with an optimization problem (7.1) a (generally nonlinear) system of equations and inequalities. (**Quiz 8.1:** In which case are the KKT conditions affine conditions?) They are the basis of most numerical constrained optimization solvers. Unfortunately, the KKT conditions are not, in general, necessary optimality conditions, since they express the condition $-\nabla f(x) \in \mathcal{T}_F^{\text{lin}}(x)^\circ$ instead of $-\nabla f(x) \in \mathcal{T}_F(x)^\circ$. The following example shows that this may actually be an issue in practice.

Example 8.5 ($\mathcal{T}_F^{\text{lin}}(x) \subsetneq \mathcal{T}_F(x)$). Consider the optimization problem

$$\begin{aligned} \text{Minimize} \quad & -x_1 \\ \text{subject to} \quad & x_2 + x_1^3 \leq 0 \\ \text{and} \quad & -x_2 \leq 0. \end{aligned} \tag{8.8}$$

The feasible set has the following shape:

Obviously, $x^* = (0, 0)^\top$ is the unique global minimizer of (8.8), and there are no further local minimizers. The inequalities g_1 and g_2 are both active in x^* , and we find

$$\begin{aligned} \nabla g_1(x) &= \begin{pmatrix} 3x_1^2 \\ 1 \end{pmatrix} & \Rightarrow & \nabla g_1(x^*) = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \\ \nabla g_2(x) &= \begin{pmatrix} 0 \\ -1 \end{pmatrix} & \Rightarrow & \nabla g_2(x^*) = \begin{pmatrix} 0 \\ -1 \end{pmatrix}. \end{aligned}$$

We evaluate

$$\begin{aligned} \mathcal{T}_F(x^*) &= \{d \in \mathbb{R}^2 \mid d_1 \leq 0, d_2 = 0\} = \mathbb{R}^- \times \{0\}, \\ \mathcal{T}_F^{\text{lin}}(x^*) &= \{d \in \mathbb{R}^2 \mid g'_i(x^*) d \leq 0, i = 1, 2\} \\ &= \{d \in \mathbb{R}^2 \mid d_2 = 0\} = \mathbb{R} \times \{0\}, \end{aligned}$$

so that we infer $\mathcal{T}_F^{\text{lin}}(x^*) \subsetneq \mathcal{T}_F(x^*)$.

The optimality condition (7.4) is satisfied as expected from Theorem 7.4:

$$f'(x^*) d = (-1 \ 0) d \geq 0 \quad \text{for all } d \in \mathcal{T}_F(x^*) = \mathbb{R}^- \times \{0\}.$$

The same variational inequality is not satisfied with the larger cone $\mathcal{T}_F^{\text{lin}}(x^*)$. Consequently, $-\nabla f(x^*)$ belongs to $\mathcal{T}_F(x^*)^\circ$ but it does not belong to $\mathcal{T}_F^{\text{lin}}(x^*)^\circ$:

$$\begin{aligned} -\nabla f(x^*) &\in \mathcal{T}_F(x^*)^\circ = \{s \in \mathbb{R}^2 \mid s_1 \geq 0\} = \mathbb{R}^+ \times \mathbb{R}, \\ -\nabla f(x^*) &\notin \mathcal{T}_F^{\text{lin}}(x^*)^\circ = \{s \in \mathbb{R}^2 \mid s_1 = 0\} = \{0\} \times \mathbb{R}. \end{aligned}$$

Consequently, the KKT conditions cannot be satisfied at x^* . Here they boil down to

$$\begin{pmatrix} -1 \\ 0 \end{pmatrix} + \mu_1 \begin{pmatrix} 0 \\ 1 \end{pmatrix} + \mu_2 \begin{pmatrix} 0 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

and they cannot be satisfied for any $\mu \in \mathbb{R}^2$, $\mu \geq 0$.

We are going to bridge the gap between $-\nabla f(x) \in \mathcal{T}_F^{\text{lin}}(x)^\circ$ and $-\nabla f(x) \in \mathcal{T}_F(x)^\circ$ by means of **constraint qualifications (CQs)**.

§ 8.1 FIRST-ORDER NECESSARY OPTIMALITY CONDITIONS UNDER THE ABADIE AND GUIGNARD CQ

Definition 8.6 (Abadie CQ and Guignard CQ⁶).

- (i) A feasible point $x \in F$ satisfies the **Abadie constraint qualification (ACQ)** in case $\mathcal{T}_F^{\text{lin}}(x) = \mathcal{T}_F(x)$.⁷
- (ii) A feasible point $x \in F$ satisfies the **Guignard constraint qualification (GCQ)** in case $\mathcal{T}_F^{\text{lin}}(x)^\circ = \mathcal{T}_F(x)^\circ$.

Note: The ACQ implies the GCQ.

Theorem 8.7 (KKT conditions are necessary optimality conditions under the Abadie CQ and the Guignard CQ).

Suppose that x^* is a local minimizer of (7.1) which satisfies the Abadie CQ or the Guignard CQ. Then $\Lambda(x^*) \neq \emptyset$, i. e., there exist Lagrange multipliers μ^* and λ^* (not necessarily unique) such that the KKT conditions (8.4) are satisfied.

Proof. As a local minimizer of (7.1), x^* is feasible of course. From Theorem 7.4 and the ACQ or GCQ we infer

$$-\nabla f(x^*) \in \mathcal{T}_F^{\text{lin}}(x^*)^\circ = \mathcal{T}_F(x^*)^\circ.$$

Lemma 8.4 confirms that this is equivalent to the KKT conditions. □

Remark 8.8 (on the significance of constraint qualifications).

⁶see Guignard, 1969 and Flegel, Kanzow, 2005, Corollary 3.8

⁷Some authors also speak of a **quasiregular point**; see Bertsekas, 1999, p.345–349.

- (i) Constraint qualifications (CQs) render the KKT conditions necessary optimality conditions. Therefore, the KKT conditions (8.4) are sometimes called a **qualified optimality system**.
- (ii) If the GCQ does not hold at a local minimizer x^* , then Lagrange multipliers may fail to exist, as we saw in [Example 8.5](#). It is also possible that they do exist, but it depends on the objective.
- (iii) CQs tell us whether the tangent cone to the feasible set admits an algebraic description in terms of the linearizing cone. The latter depends on our **description** of the feasible set F in terms of inequality and equality constraints. Two different descriptions of the same feasible set may differ w.r.t. the CQs they satisfy.
- (iv) A general weakness of CQs is that they need to be checked at the point x^* , which is usually a priori unknown. Algorithms searching for KKT points may miss minimizers which fail to satisfy a CQ.
- (v) The verification of the ACQ or GCQ is often cumbersome. Therefore, we will later introduce stronger CQs which are easier to handle and which imply the ACQ.
- (vi) In the absence of CQs, one arrives at **Fritz-John conditions (FJ conditions)**⁸

$$\mu_0 \nabla f(x) + g'(x)^\top \mu + h'(x)^\top \lambda = 0, \quad (8.9a)$$

$$h(x) = 0, \quad (8.9b)$$

$$\mu \geq 0, \quad g(x) \leq 0, \quad \mu^\top g(x) = 0, \quad (8.9c)$$

$$\mu_0 \geq 0. \quad (8.9d)$$

A point x is termed a **Fritz-John point** for problem (7.1) if there exist (μ_0, μ, λ) which are not all zero, such that (x, μ_0, μ, λ) satisfy the FJ conditions (8.9).

One calls (8.9) an **unqualified optimality system** since one can show—without assuming any CQ—that any local minimizer of (7.1) is an FJ point; see for instance [Geiger, Kanzow, 2002](#), p.72. In case we happen to have $\mu_0 > 0$, we can re-normalize the vector (μ_0, μ, λ) so that $\mu_0 = 1$ holds, and we have indeed a KKT point.

§ 8.2 FIRST-ORDER NECESSARY OPTIMALITY CONDITIONS UNDER AFFINE CONSTRAINTS

We consider a special case of problem (7.1) which has only affine (“linear”) constraints.

$$\left. \begin{array}{ll} \text{Minimize} & f(x) \\ \text{subject to} & A_{\text{ineq}} x \leq b_{\text{ineq}} \\ \text{and} & A_{\text{eq}} x = b_{\text{eq}} \end{array} \right\} \quad \text{where } x \in \mathbb{R}^n \quad (8.10)$$

⁸[John, 1948](#)

with $A_{\text{ineq}} \in \mathbb{R}^{n_{\text{ineq}} \times n}$ and $A_{\text{eq}} \in \mathbb{R}^{n_{\text{eq}} \times n}$ as well as $b_{\text{ineq}} \in \mathbb{R}^{n_{\text{ineq}}}$ and $b_{\text{eq}} \in \mathbb{R}^{n_{\text{eq}}}$. The KKT conditions associated with (8.10) read

$$\nabla f(x) + A_{\text{ineq}}^T \mu + A_{\text{eq}}^T \lambda = 0, \quad (8.11a)$$

$$A_{\text{eq}} x - b_{\text{eq}} = 0, \quad (8.11b)$$

$$\mu \geq 0, \quad A_{\text{ineq}} x - b_{\text{ineq}} \leq 0, \quad \mu^T (A_{\text{ineq}} x - b_{\text{ineq}}) = 0. \quad (8.11c)$$

Theorem 8.9 (KKT conditions are necessary optimality conditions under affine constraints only). *Suppose that x^* is a local minimizer of (8.10). Then $\Lambda(x^*) \neq \emptyset$, i. e., there exist Lagrange multipliers μ^* and λ^* (not necessarily unique) such that the KKT conditions (8.11) are satisfied.*

Proof. When the feasible set F is described exclusively in terms of affine constraints, one can show that the Abadie CQ holds at every feasible point. \square

The observation that affine constraints imply the ACQ everywhere is the reason why one does not explicitly require CQs in linear optimization; compare [Herzog, 2022](#), § 8.

End of Week 8

§ 8.3 FIRST-ORDER NECESSARY OPTIMALITY CONDITIONS UNDER MFCQ

Definition 8.10 (Mangasarian-Fromovitz Constraint Qualification).

A feasible point $x \in F$ satisfies the **Mangasarian-Fromovitz constraint qualification (MFCQ)** if the following conditions hold:

(i) The gradients $\{\nabla h_j(x)\}_{j=1}^{n_{\text{eq}}}$ are linearly independent. In other words, the Jacobian $h'(x)$ has full row rank (is surjective).

(ii) There exists a vector $d \in \mathbb{R}^n$ such that

$$\begin{aligned} g'_i(x) d &< 0 \quad \text{for all } i \in \mathcal{A}(x), \\ h'_j(x) d &= 0 \quad \text{for all } j = 1, \dots, n_{\text{eq}}. \end{aligned} \quad (8.12)$$

The vector d from (8.12) is sometimes called an **MFCQ vector**. Notice that **condition (i)** implies $0 \leq n_{\text{eq}} \leq n$, i. e., there cannot be too many equality constraints.

Lemma 8.11 (alternative formulation of **condition (ii)**). *Suppose that x is a feasible point for (7.1). Then the following are equivalent to **condition (ii)**:*

(iii) There exists a vector $d \in \mathbb{R}^n$ such that

$$\begin{aligned} g(x) + g'(x) d &< 0, \\ h(x) + h'(x) d &= 0. \end{aligned} \quad (8.13)$$

(iv) There exists a vector $d \in \mathbb{R}^n$ such that

$$\begin{aligned} g'_i(x) d &\leq -1 && \text{for all } i \in \mathcal{A}(x), \\ h'_j(x) d &= 0 && \text{for all } j = 1, \dots, n_{\text{eq}}. \end{aligned} \quad (8.14)$$

Proof.

□

Remark 8.12 (on the Mangasarian-Fromovitz CQs). *We can numerically verify the MFCQ at a feasible point x as follow.*

- (i) *We determine the row rank of $h'(x)$, e. g., by computing its singular values.*
- (ii) *We verify whether or not the linear optimization problem with zero objective and constraints as in (8.14) is feasible.⁹*

Lemma 8.13 (MFCQ implies existence of a feasible curve).

Suppose that \bar{x} is a feasible point for (7.1) which satisfies the MFCQ with the MFCQ vector d . Then there exists $\varepsilon > 0$ and a curve $\gamma: (-\varepsilon, \varepsilon) \rightarrow \mathbb{R}^n$ with the following properties:

(i) γ is of class C^1 on $(-\varepsilon, \varepsilon)$.

$$(ii) \quad \gamma \text{ satisfies } \begin{cases} h(\gamma(t)) = 0 & \text{for } t \in (-\varepsilon, \varepsilon), \\ g(\gamma(t)) \leq 0 & \text{for } t \in [0, \varepsilon), \\ g(\gamma(t)) < 0 & \text{for } t \in (0, \varepsilon). \end{cases}$$

(iii) $\gamma(0) = \bar{x}$ and $\dot{\gamma}(0) = d$.

Proof. In the absence of equality constraints, we simply set $\gamma(t) := \bar{x} + t d$ on some interval $(-\varepsilon_0, \varepsilon_0)$; then $\gamma(0) = \bar{x}$ and $\dot{\gamma}(0) = d$ hold. Otherwise, we will apply the implicit function theorem to show the existence of the curve γ with the desired properties. The curve will be constructed using only the equality constraints. However, we cannot apply the implicit function theorem directly to $h(\gamma(t)) = 0$ since the number of equality constraints n_{eq} is generally smaller than the dimension n . As a remedy, we consider a least-squares problem where we require $\gamma(t)$ to stay as close as possible to the line $t \mapsto \bar{x} + t d$ while satisfying the equality constraints. This leads us to consider the family of problems

$$\begin{aligned} &\text{Minimize} && \frac{1}{2} \|\bar{x} - (\bar{x} + t d)\|^2, && \text{where } \bar{x} \in \mathbb{R}^n \\ &\text{subject to} && h(\bar{x}) = 0, \end{aligned} \quad (*)$$

where $t \in \mathbb{R}$ acts as a parameter. The Lagrangian associated with (*) is

$$\mathcal{L}(x, \lambda) = \frac{1}{2} \|x - (\bar{x} + t d)\|^2 + \lambda^\top h(x)$$

⁹Further reading: [Burke, 2014](#), Ch.7.2, p.76, who also discusses the dual of this LP.

and therefore, we obtain the KKT conditions

$$\begin{aligned} x - (\bar{x} + t d) + h'(x)^\top \lambda &= 0, \\ h(x) &= 0. \end{aligned}$$

We apply the implicit function theorem “to the KKT conditions”, i. e., to the function

$$H(x, \lambda, t) := \begin{pmatrix} x - (\bar{x} + t d) + h'(x)^\top \lambda \\ h(x) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

and seek to resolve $\begin{pmatrix} x \\ \lambda \end{pmatrix}$ as a function of the problem parameter t . We refer to this function as $\begin{pmatrix} \gamma(t) \\ \xi(t) \end{pmatrix}$.

We know that for $t = 0$, $x = \bar{x}$ is the unique global minimizer of (*). Moreover, the MFCQ is satisfied for problem (*) at $x = \bar{x}$ since the constraints are a subset of the constraints of (7.1). Therefore, there exists an associated Lagrange multiplier $\bar{\lambda}$.

At the nominal parameter value $t = 0$, $H(\bar{x}, \bar{\lambda}, 0) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$ holds. To apply the implicit function theorem, we need to show that the partial Jacobian of H w.r.t. (x, λ) is invertible at the point $(\bar{x}, \bar{\lambda}, 0)$. This Jacobian reads

$$H_{(x,\lambda)}(x, \lambda, t) = \begin{bmatrix} \text{Id} & h'(x)^\top \\ h'(x) & 0 \end{bmatrix} \quad \text{and thus} \quad H_{(x,\lambda)}(\bar{x}, \bar{\lambda}, 0) = \begin{bmatrix} \text{Id} & h'(\bar{x})^\top \\ h'(\bar{x}) & 0 \end{bmatrix}.$$

Using the surjectivity of $h'(\bar{x})$, we can show that the latter matrix is invertible (**Quiz 8.2:** Can you show this?). Therefore, the implicit function theorem is applicable and it yields the existence of an $\varepsilon_0 > 0$ and curves $\begin{pmatrix} \gamma \\ \xi \end{pmatrix} : (-\varepsilon_0, \varepsilon_0) \rightarrow \mathbb{R}^n \times \mathbb{R}^{n_{\text{eq}}}$ such that $H(\gamma(t), \xi(t), t) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$ holds as well as $\begin{pmatrix} \gamma(0) \\ \xi(0) \end{pmatrix} = \begin{pmatrix} \bar{x} \\ \bar{\lambda} \end{pmatrix}$. Moreover, $\begin{pmatrix} \gamma \\ \xi \end{pmatrix}$ is of class C^1 with

$$\begin{bmatrix} \text{Id} & h'(\bar{x})^\top \\ h'(\bar{x}) & 0 \end{bmatrix} \begin{pmatrix} \dot{\gamma}(0) \\ \dot{\xi}(0) \end{pmatrix} = -H_t(\bar{x}, \bar{\lambda}, 0) = \begin{pmatrix} d \\ 0 \end{pmatrix}. \quad (**)$$

The first equation in (**) reads

$$\dot{\gamma}(0) = d - h'(\bar{x})^\top \dot{\xi}(0)$$

and thus

$$h'(\bar{x}) \dot{\gamma}(0) = h'(\bar{x}) d - h'(\bar{x}) h'(\bar{x})^\top \dot{\xi}(0).$$

By the second equation in (**) and the properties of the MFCQ vector, see (8.12), we infer

$$0 = 0 - h'(\bar{x}) h'(\bar{x})^\top \dot{\xi}(0).$$

The matrix $h'(\bar{x}) h'(\bar{x})^\top \in \mathbb{R}^{n_{\text{eq}} \times n_{\text{eq}}}$ is s. p. d. (**Quiz 8.3:** Can you argue why?) and thus $\dot{\xi}(0) = 0$ holds. Inserting this back into the first equation of (**) shows $\dot{\gamma}(0) = d$.

It remains to show $g(\gamma(t)) \leq 0$ for $t \in [0, \varepsilon_0)$ and the strict inequality when $t \in (0, \varepsilon_0)$. When $i \in \{1, \dots, n_{\text{ineq}}\}$ is an inactive index at x , i. e., $g_i(x) < 0$, then by continuity, there exists $\varepsilon_i > 0$ such that

$$g_i(\gamma(t)) < 0 \quad \text{for all } t \in (-\varepsilon_i, \varepsilon_i).$$

By contrast, when i is an active index at x , i. e., $g_i(x) = 0$, let us abbreviate $\varphi(t) := g_i(\gamma(t))$. By the chain rule, this function is of class C^1 . Then $\varphi(0) = g_i(\gamma(0)) = g_i(\bar{x}) = 0$ holds as well as

$$\begin{aligned}\dot{\varphi}(t) &= g'_i(\gamma(t)) \dot{\gamma}(t) \\ \text{and thus } \dot{\varphi}(0) &= g'_i(\gamma(0)) \dot{\gamma}(0) \\ &= g'_i(\bar{x}) d < 0.\end{aligned}$$

The properties $\varphi(0) = 0$ and $\dot{\varphi}(0) < 0$ and the continuity of $\dot{\varphi}$ imply that there exists $\varepsilon_i > 0$ such that $\varphi(t) \leq 0$ holds for all $t \in [0, \varepsilon_i]$ and even $\varphi(t) < 0$ for all $t \in (0, \varepsilon_i)$.

Choosing $\varepsilon := \min\{\varepsilon_0, \varepsilon_1, \dots, \varepsilon_{n_{\text{ineq}}}\}$ yields **Statement (ii)**. □

Corollary 8.14 (MFCQ implies ACQ).

Suppose that x is a feasible point for (7.1) which satisfies the MFCQ. Then the ACQ holds at x .

Proof. We need to show $\mathcal{T}_F^{\text{lin}}(x) = \mathcal{T}_F(x)$. The inclusion $\mathcal{T}_F(x) \subseteq \mathcal{T}_F^{\text{lin}}(x)$ follows from **Lemma 7.7**. We only need to show the reverse inclusion $\mathcal{T}_F^{\text{lin}}(x) \subseteq \mathcal{T}_F(x)$.

To this end, let $d_0 \in \mathcal{T}_F^{\text{lin}}(x)$ be arbitrary and let d be an MFCQ vector, i. e., we have

$$\begin{aligned}g'_i(x) d_0 &\leq 0 \text{ and } g'_i(x) d < 0 & \text{for all } i \in \mathcal{A}(x), \\ h'_j(x) d_0 &= 0 \text{ and } h'_j(x) d = 0 & \text{for all } j = 1, \dots, n_{\text{eq}}.\end{aligned}$$

We set $d(\tau) := d_0 + \tau d$ for $\tau > 0$. Then

$$\begin{aligned}g'_i(x) d(\tau) &< 0 & \text{for all } i \in \mathcal{A}(x), \\ h'_j(x) d(\tau) &= 0 & \text{for all } j = 1, \dots, n_{\text{eq}}.\end{aligned}$$

That is, $d(\tau)$ is also an MFCQ vector.

We show $d(\tau) \in \mathcal{T}_F(x)$ for any fixed $\tau > 0$. **Lemma 8.13** implies the existence of a curve $\gamma: (-\varepsilon, \varepsilon) \rightarrow \mathbb{R}^n$ such that $\gamma(t) \in F$ holds for $t \in [0, \varepsilon]$ and $\gamma(0) = x$ as well as $\dot{\gamma}(0) = d(\tau)$. To show that $d(\tau) \in \mathcal{T}_F(x)$ holds, let $t^{(k)} \in (0, \varepsilon)$ be any sequence with $t^{(k)} \searrow 0$ and $x^{(k)} := \gamma(t^{(k)}) \in F$.

Then we have $x^{(k)} \rightarrow \gamma(0) = x$ and

$$d(\tau) = \dot{\gamma}(0) = \lim_{k \rightarrow \infty} \frac{\gamma(t^{(k)}) - \gamma(0)}{t^{(k)}} = \lim_{k \rightarrow \infty} \frac{x^{(k)} - x}{t^{(k)}},$$

which confirms $d(\tau) \in \mathcal{T}_F(x)$ for any $\tau > 0$. Since $\mathcal{T}_F(x)$ is closed by **Lemma 7.3**, the limit point $d_0 = \lim_{\tau \searrow 0} d(\tau)$ belongs to $\mathcal{T}_F(x)$ as well. □

Theorem 8.15 (KKT conditions are necessary optimality conditions under the MFCQ).

Suppose that x^ is a local minimizer of (7.1) which satisfies the MFCQ. Then $\Lambda(x^*) \neq \emptyset$, i. e., there exist Lagrange multipliers μ^* and λ^* (not necessarily unique) such that the KKT conditions (8.4) are satisfied. The set of Lagrange multipliers $\Lambda(x^*)$ is **compact**.*

Proof. The existence of Lagrange multipliers follows directly from the combination of [Corollary 8.14](#) and [Theorem 8.7](#). We do not give a proof of compactness here. \square

§ 8.4 FIRST-ORDER NECESSARY OPTIMALITY CONDITIONS UNDER LICQ

Definition 8.16 (Linear Independence Constraint Qualification).

A feasible point $x \in F$ satisfies the **linear independence constraint qualification (LICQ)** if the gradients $\{\nabla h_j(x)\}_{j=1}^{n_{\text{eq}}} \cup \{\nabla g_i(x)\}_{i \in \mathcal{A}(x)}$ are linearly independent.¹⁰

Notice that the LICQ implies $0 \leq n_{\text{eq}} + |\mathcal{A}(x)| \leq n$, i. e., there cannot be too many equality plus active inequality constraints.

Lemma 8.17 (LICQ implies MFCQ).

Suppose that x is a feasible point for (7.1) which satisfies the LICQ. Then the MFCQ holds at x .

Proof. The LICQ directly implies [condition \(i\)](#) in [Definition 8.10](#) since any subset of linearly independent vectors is linearly independent as well. Define

$$A := \begin{bmatrix} g'_i(x)|_{i \in \mathcal{A}(x)} \\ h'_j(x)|_{j=1, \dots, n_{\text{eq}}} \end{bmatrix} \quad \text{and} \quad b := \underbrace{(-1, \dots, -1)}_{|\mathcal{A}(x_0)|}, \underbrace{(0, \dots, 0)}_{n_{\text{eq}}}^\top.$$

The rows of A are linearly independent, hence A is surjective so that $A d = b$ has a solution $d \in \mathbb{R}^n$. This vector d satisfies (8.14) and thus it also satisfies [condition \(ii\)](#) of [Definition 8.10](#). \square

Theorem 8.18 (KKT conditions are necessary optimality conditions under the LICQ).

Suppose that x^* is a local minimizer of (7.1) which satisfies the LICQ. Then $\Lambda(x^*)$ is a singleton, i. e., there exist **uniquely defined** Lagrange multipliers μ^* and λ^* such that the KKT conditions (8.4) are satisfied.

Proof. By [Lemma 8.17](#), the MFCQ holds at x^* , so that the set $\Lambda(x^*)$ of Lagrange multipliers is non-empty (and compact) by [Theorem 8.15](#). It remains to show the uniqueness. Due to the complementarity system (8.4c), the components of μ^* corresponding to inactive constraints must be 0. These components can therefore be removed from the linear system, and (8.5) reduces to

$$\begin{bmatrix} g'_i(x)|_{i \in \mathcal{A}(x)} \\ h'_j(x)|_{j=1, \dots, n_{\text{eq}}} \end{bmatrix}^\top \begin{pmatrix} \mu_i^*|_{i \in \mathcal{A}(x)} \\ \lambda_j^*|_{j=1, \dots, n_{\text{eq}}} \end{pmatrix} = -\nabla f(x).$$

The LICQ states that the matrix (without the transpose sign) has full row rank and hence the system matrix (including the transpose sign) has full column rank. This implies that μ^* and λ^* must be unique. \square

¹⁰Some authors also speak of a **regular point**; see [Bertsekas, 1999](#), p.349.

We summarize the relations between the various constraint qualifications:

$$\boxed{\text{LICQ}} \xRightarrow{\text{Lemma 8.17}} \boxed{\text{MFCQ}} \xRightarrow{\text{Corollary 8.14}} \boxed{\text{ACQ}} \xRightarrow{\text{Definition 8.6}} \boxed{\text{GCQ}} \quad (8.15)$$

The reverse relations do not hold in general. However, for problems without inequality constraints, LICQ and MFCQ are identical (and $d = 0$ is an MFCQ vector). All CQs ensure that the KKT conditions are necessary optimality conditions for local minimizers, i. e., CQ ensure the existence of Lagrange multipliers. Under the MFCQ, the set of multipliers is compact, and the multipliers are unique under the LICQ.
